## **INTRODUCTION**

The SF-CHAMP travel demand forecasting model is one of the first activity-based modeling systems used in the U.S., and the only activity-based model in the U.S. used for ongoing and extensive policy analysis on a wide variety of planning studies—from local impact assessments to New Starts analysis. As part of an on-call services contract, PB was engaged to provide services related to the enhancement and update of the SF-CHAMP model system. The services included tasks specifically intended to make it easier to set up and use the model system through the development of automated tools, as well as take advantage of recent data including an expanded TAZ system, refined employment estimates, highway and transit observed speed data, 2004 Muni on-board survey data, and 2000 BATS home-interview survey data. Ultimately, this effort resulted in a model system that is easier to use, matches observed data better than the previous model, and provides more accurate policy responses than the previous version of the model.

This document describes the tasks undertaken as part of this effort as well as the results of model calibration and validation.

## **EXPANDED TRAVEL ANALYSIS ZONE SYSTEM**

Prior to undertaking the refreshing and updating of the core San Francisco Model components, more zones were added to the San Francisco Model system. A total of 215 additional zones were added in San Francisco, and 294 additional zones were added outside San Francisco. The purpose of increasing the number of zones and improving the spatial resolution of the model was to provide greater model sensitivity in areas of the City expected to experience significant population and employment growth in the coming decades. These areas are primarily located on the Bayshore side of the City, including the Bayview and Hunters Point neighborhoods, Candlestick, the Third Street corridor, Mission Bay and South of Market. The original zone system within the city of San Francisco was based on Census Journey-to-Work TAZs, and included many relatively large TAZs in the areas identified, making detailed project analysis difficult. Within San Francisco, the new

TAZ system is based on 2000 Census block group definitions. Where Census block groups were too big, smaller TAZs are based on Census blocks. In some areas of the City, such as the Presidio, Treasure Island, and Golden Gate Park, even the Census block definitions were too large, and SFCTA staff manually disaggregated these areas into smaller TAZs.

The San Francisco Model's geographic extent includes the entire Bay Area. For areas outside San Francisco, the SF Model's TAZs and networks are based on MTC's regional Baycast model. Since the original development of the San Francisco Model, MTC has added more zones to the other eight Bay Area counties. These new TAZs outside San Francisco have been incorporated into the new SF TAZ system, and are approximately the size of census tracts. Figure 1 illustrates the new SF Model TAZ boundaries. Figure 2 illustrates the old SF Model TAZ boundaries.

**Figure 1: New SF Model TAZs**

**Figure 2: Old SF Model TAZs**

## **REVISED BASE YEAR (2000) SOCIOECONOMIC & EMPLOYMENT INPUTS**

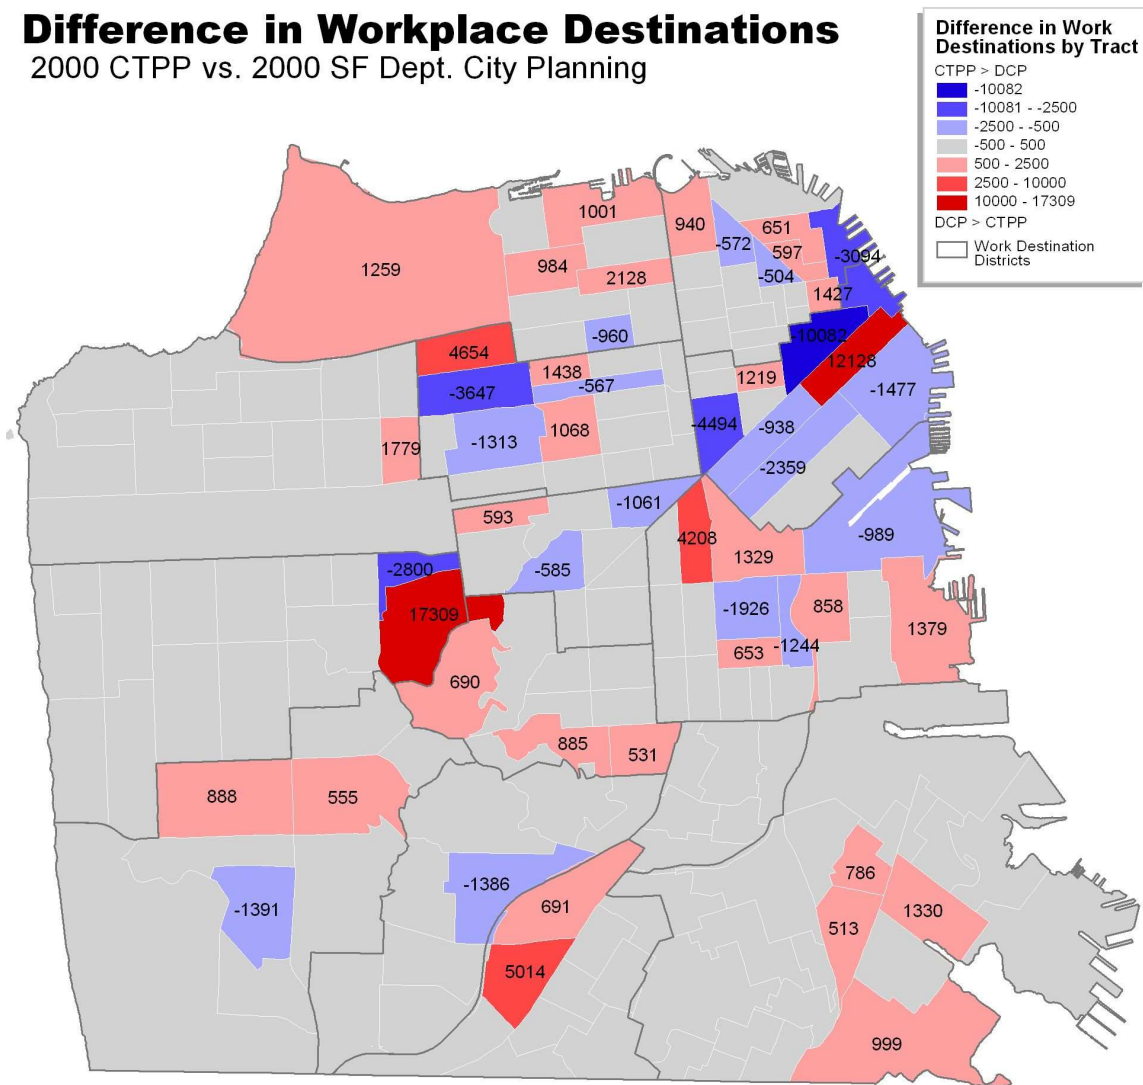

New socioeconomic and employment data were developed to reflect the new TAZ boundary definitions. New 2000 TAZ-level totals of households, household population, group quarters population, and employed residents were based on 2000 Census block information. The development of group quarters population estimates, which were not present in the original San Francisco Model, is necessary in order to include these people in the synthetic population input to the model. New 2000 TAZ-level employment estimates were created by reallocating by area the old TAZ-level employment estimates, which had been prepared by the San Francisco Planning Department.

Adjustments to the new TAZ-level employment estimates were made as a result of large differences between the modeled and observed workplace destinations identified in the process of calibrating the workplace destination choice model. Part 3 of the Census Transportation Planning Package (or “Journey-to-Work”) was a key source of observed workplace destination data used for model calibration. Figure 3 illustrates the differences (at a census tract level) between the employment inputs based on Planning Department data, and the work destinations reported in the CTPP. This map shows that there were 3 tracts where the differences between the two sources was more than 10,000 jobs, and another 7 tracts where the differences between the two sources was more than 2,500 jobs. These discrepancies hindered the workplace destination choice calibration effort, and called into question the integrity of the TAZ-level employment assumptions.

Figure 3 Comparison of CTPP and SF Planning Dept Employment Locations

### Difference in Workplace Destinations

2000 CTPP vs. 2000 SF Dept. City Planning

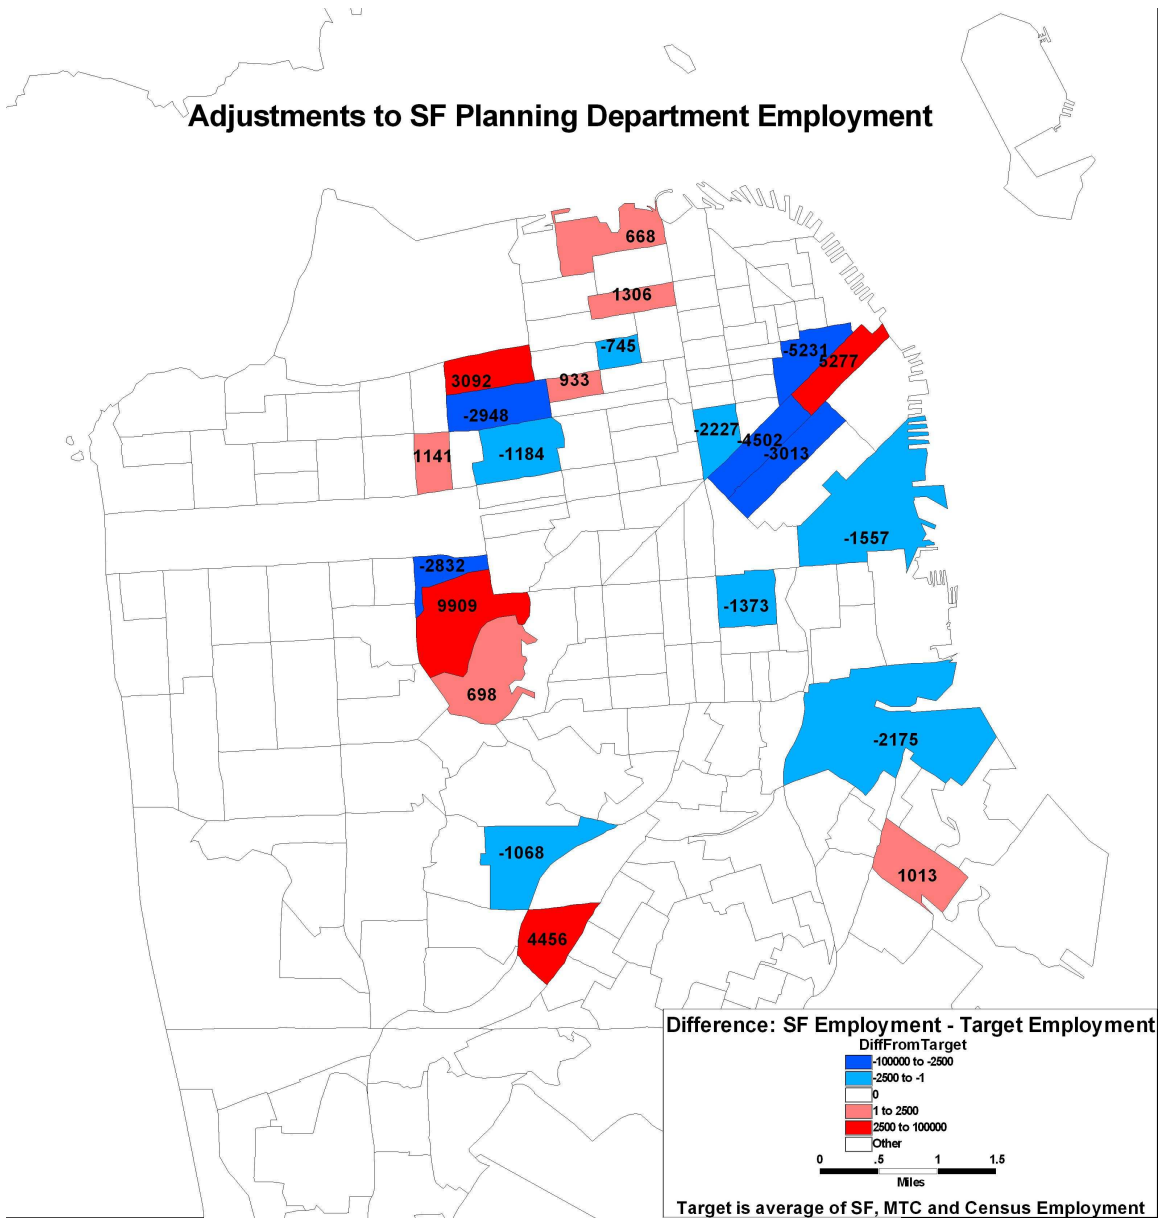

In order to evaluate the reasonableness of these assumptions, the Planning Department-based data were compared, at a Census tract-level, to the CTPP and MTC employment data for San Francisco. Frequently, two of three data sources were in agreement for a given TAZ, but which two sources agreed varied by TAZ. This led to use of a "best two out of three" rule, where if the Planning Department-based numbers agreed (within 1,000 jobs at a tract level) with either the MTC number or the CTPP number it was maintained, but if both the MTC and CTPP numbers were different from the Planning Department number (by more than 1,000), then the Planning Department numbers for TAZs within that tract were adjusted.

Using the difference criteria described above, TAZs in 19 tracts were adjusted.

Additionally, analyst review of the data identified three additional tracts that were adjusted manually. The adjustments were made by taking the average of the three sources at a tract level, developing a factor based on this new tract total and the original Planning Department tract total, and applying this factor to all TAZs within the tract. These adjustments resulted in a reallocation of employment geographically, with increases in Downtown, Potrero, and the Bayview, and with decrease in the Marina, Sunset and Richmond districts. The countywide distribution of employment by sector was little changed, with a reduction of the CIE (cultural, institutional, educational) and MED (medical) sectors, and slight increases in all the other sectors.

**Figure 4: Adjusted San Francisco Planning Dept Employment by Tract**

**Revised Future Year (2005, 2015, 2025, 2030) Socioeconomic & Employment Inputs**

In addition to developing new base year socioeconomic and employment inputs reflective of the more detailed TAZs for the San Francisco Model, it was also necessary to create new future year socioeconomic and employment inputs. For TAZs within San Francisco, future year household and population estimates were developed by estimating growth factors

derived from base year and future year MTC and ABAG tract-level data, and applying these factors to the Census-based year 2000 TAZ data. Manual adjustments were made to the future year assumptions for TAZs with no households or population in the year 2000, but which are expected to receive growth in future years. Future year population and socioeconomic inputs for non-San Francisco TAZs were derived directly from MTC's Baycast model zone data. The group quarters population in each TAZ is taken from the MTC model zone data (ZMAST) as the difference between total population and population in households.

Future year employment assumptions for San Francisco TAZs were developed in a slightly different manner. Rather than build future year assumptions by pivoting off of the base year, new future year TAZ-level employment estimates were created by reallocating by area the old CHAMP2 TAZ-level employment estimates, which had been prepared by the San Francisco Planning Department. Future year employment assumptions for non-San Francisco TAZs were derived directly from MTC's Baycast model zone data.

## TAZ DATA PROCESSING

### TAZDATA file

A key input to the San Francisco Model is a TAZ-based datafile containing population and employment totals as described above, as well as other zone information, such as parking costs, household incomes, pedestrian environment factors, and many other critical attributes. This file includes information for all TAZs in the model system, which covers the entire Bay Area. The information in the TAZ data file is derived from multiple sources, including the San Francisco County Transportation Authority, the San Francisco Planning Department, and MTC. The attributes for San Francisco zones are in most cases different than the attributes for non-San Francisco zones. For example, the employment sectors for San Francisco zones are consistent with the categories defined by the Planning Department in the 1998 Citywide Land Use Study. This sector information is not available for Bay Area counties outside San Francisco. For non-San Francisco zones, the employment sectors are consistent with those used by MTC in the regional BAYCAST model. Table 1 shows the fields TAZDATA fields, their source data for the San Francisco zones and for the non-San Francisco zones, and any notes on how they are calculated.

### Allocation Files

The San Francisco Model relies on MTC's regional Baycast model for forecasts of intercounty movements, but the regional Baycast model produces traditional trip-based forecasts at a more aggregate geographic scale within San Francisco. In order to address the differences in TAZ geography in San Francisco, MTC trips are reallocated to the more fine-grained San Francisco zones.

For highway trips the allocation process first aggregates trips to a district level, and then disaggregates them to a San Francisco TAZ level. It is necessary to aggregate to the district level because significant differences have been observed between MTC MTAZ-level households and employment and San Francisco-based MTAZ-level households and employment within the City. Aggregating and disaggregating compensates for these differences. Transit trips are allocated directly from the MTC zones to the San Francisco zones to maintain the spatial distribution of transit trips to the greatest degree possible. This is important due to the sensitive nature of transit trips to walking distances, and access to specific transit lines.

A separate aggregation and disaggregation process is used to allocate workers living outside San Francisco to their appropriate work TAZ within San Francisco. The results of this process are used by the shadow pricing mechanism of the workplace location choice model to ensure that the intra-county workers are assigned appropriate work locations.

### **TAZDATA TOOL**

As part of the CHAMP3 update effort, a software tool was developed to automate the process of combining data from multiple sources to produce the required model inputs. The software is implemented as a Java program, and its usage is described below. The tool creates two types of outputs: A TAZ data file for all zones in the SF Model system containing critical attributes used in the model system; and a set of "allocation" files that support the reallocation of MTC Model trips at the MTC TAZ-level to the more fine-grained SF Model TAZ-level. The preparation of both types of files is automated in the TAZDATA tool. The tool creates five primary model input files:

- TAZDATA.DBF: The main output file with contents shown in Table 1, as specified in the TazKey (described below).
- MTC\_disaggregation.csv: This file is used by TP+ matrix module to disaggregate the school, other, and non-transit work trips. It contains 4 fields: 1) district, 2) TAZ, 3) shareX100 of total district households within the TAZ, and 4) shareX100 of total district employment within the TAZ. The purpose of this file is to reallocate total home-based district-level trips to TAZs using share of district households at the production end and share of district employment at the attraction end. The first 981 records of this file should reflect the San Francisco TAZ distributions. The remaining records are for non-San Francisco zones. For these records the second field contains the TAZ number, but the shares in columns 3 and 4 are all 100.
- MTC\_disaggregation\_nhb.csv: This file is used by the TP+ matrix module to disaggregate non-home based trips. This is similar to the previous file, except that the share of district level employment is used at both the production and the attraction side. It contains 4 fields: 1) district, 2) TAZ, 3) shareX100 of total district employment within the TAZ, and 4) shareX100 of total district employment within the TAZ. As with the previous file, the first 981 records of this file should reflect the San Francisco TAZ distributions. The remaining records are for non-San Francisco zones. For these records the second field contains the TAZ number, but the shares in columns 3 and 4 are all 100.

- Allocate\_nhb.csv: Prior to identifying the NHB trips made within San Francisco by non-San Francisco residents (by time period, mode, and origin and destination areatype), this file is used by the SF-CHAMP model to disaggregate NHB trips from the MTAZ level to the SFTAZ level. This file is also used to disaggregate the work trips using transit directly from the MTCAZ level to the SFTAZ level in order to preserve reflect the availability of transit embedded in the regional mode choice model outputs. This file contains 4 fields: 1) MTAZ, 2) TAZ, 3) shareX100 of total MTAZ employment within the TAZ, and 4) shareX100 of total MTAZ employment within the TAZ. The first 981 records of this file should reflect the San Francisco TAZ distributions. The remaining records are for non-San Francisco zones. For these records the second field contains the TAZ number, but the shares in columns 3 and 4 are all 100.
  
- MTC\_disaggregation\_hbw.csv: This file is used to support the shadow pricing mechanism of the workplace destination choice model. Non-resident HBW trips attractions in San Francisco are first aggregated to the county as a whole, then disaggregated to a specific work TAZ using this file. This process ensures that the workplace location choice shadow pricing has an appropriate number of jobs to fill with residents in the right locations. It contains 4 fields: 1) County ID, 2) TAZ, 3) shareX100 of total county households within the TAZ, and 4) shareX100 of total county size within the TAZ. For creating this process, a special size term was estimated based on the different employment categories. The size terms are:
  - o sizeSFMIPS = 0.5980
  - o sizeSFPDR = 0.4582
  - o sizeSFRet = 0.7298
  - o sizeSFCIE = 0.0950
  - o sizeSFMed = 0.0950
  - o sizeSFVisitor= 0.0950
  - o sizeMTCTotal = 1.0000

Using the TAZDATA tool

## *Running the Program*

The program is run by calling the DOS batch file 'ProcessTazData.bat'.

## *Input Files*

The program runs with five main input files:

- sfzones.csv – Comma-separated value file with San Francisco TAZ-level data, including households, population, employment by sector, pedestrian environment factors, and other TAZ-level attributes for the 981 zones that represent San Francisco in the model. The sfzones.csv file should have column headers defining the contents of each field.
  
- ZMASTXX.DAT: Fixed format text file with MTC's regional Baycast model TAZ-level data, including households, population, employment by sector, income distributions and other TAZ-level attributes for all 1454 zones that represent the Bay Area (XX refers to a give forecast year, such as 00 or 25). This file requires a dictionary file defining the contents of each field. The dictionary file is a CSV file with one record for each field in the main data file. It has the same name as the data file, but with the extension .DCT. The dictionary file has the following fields:
  - o COLUMN – The name of the field.
  - o START – The starting position of the field, one-based and inclusive.
  - o END – The ending position of the field, one-based and inclusive.
  - o TYPE – Either NUMBER or STRING depending on the type of the field.
  - o LABELINFILE – Either 1 or 0, indicating whether or not the first row of the main data file includes column headers.

- HBSSCHOOL.ZENROLL.DAT – Fixed format text file with estimated school enrollment for MTC TAZs. This file requires a dictionary file defining the contents of each field (see above for description of dictionary file structure).
  
- AZLOS.DAT: Fixed format text file with area type information for MTC TAZs. This file requires a dictionary file defining the contents of each field(see above for description of dictionary file structure).
  
- TAZKEY.CSV: Critical file that defines how the other input files are combined to produce the output TAZDATA file. The relationships are specified in this table such that they can be changed without re-compiling the code. TZKEY is in CSV format, with one record for each field desired in the output file, and the following columns:
  - o Column – Numerical position of the output column.
  - o OutputField – Desired name of the output field.
  - o Decimals – Number of decimals in the output table, only relevant for DBF outputs.
  - o Scaling – For each row in the output column, the values in factor fields are scaled such that their sum matches the value in the total field.
  - o SFZoneTable – Defines the input table from which values will be taken to fill that output field for zones within San Francisco. Must be sfzones, azlos, zmast, or enroll.
  - o SFZoneField – Defines the input column from which values will be taken to fill that output field for zones within San Francisco.
  - o SFFactor – Factor used to scale the output for zones within San Francisco.

- NonSFZoneTable – Defines the input table from which values will be taken to fill that output field for zones outside San Francisco. Must be sfzones, azlos, zmast, or enroll.
- NonSFZoneField – Defines the input column from which values will be taken to fill that output field for zones outside San Francisco.
- NonSFFactor – Factor used to scale the output for zones outside San Francisco.

### *Controls*

The controls include the JAR files with the Java classes, a log4j.xml file that specifies how logging will be performed, and the tazdata.properties file that specifies file names and other model parameters. The properties file is the only of these that may need to be modified, and includes:

- Tazkey: Name of the TazKey file.
- Sfzones: Name of the sfzones file.
- Zmast: Name of the zmast file.
- Azlos: Name of the azlos file.
- Enroll: Name of the enroll file
- numZonesInsideSF: Number of TAZs inside San Francisco (981).
- numZonesOutsideSF: Number of TAZs outside San Francisco (1264).
- numExternalStations: Number of external stations (21).
- tazkeyIndex: Column used as an index in TazKey file.
- sfzonesIndex: TAZ column used as an index in sfzones file
- zmastIndex: TAZ column used as an index in zmast file
- azlosIndex: TAZ column used as an index in azlos file
- enrollIndex: TAZ column used as an index in enroll file
- mtczoneEquivField: Name of column containing the MTC zone ID in the sfzones file
- firstNonSfZone: First MTC zone in zmast file that is outside San Francisco
- zmastSfTazConversion: Value added to MTC zone IDs outside San Francisco to get the SF zone ID

- districtField: Field in the output file containing the district ID for disaggregation.
- mtcTazField: Field in the output file containing the MTC TAZ ID for disaggregation
- hhField: Field in output file containing the number of households, used for disaggregation
- empField: Field in output file containing the total employment, used for disaggregation
- outputFile: Name of output file
- disagOutFile: Name of the disaggregation file for home-based trips
- nhbDisagOutFile: Name of the disaggregation file for non-home-based trips.
- allocateOutFile: Name of the allocation file for non-home-based trips
- outputFileType: Type of the main output file, either DBF or CSV.

### *Output Files*

The program produces the following output files:

- tazdata.dbf – The main output file containing the data specified in the TazKey.
- MTC\_disaggregation.csv - This file is used by TP+ matrix module to disaggregate the school, and other trips. In contains 4 fields: 1) District, 2) TAZ, 3) shareX100 of total District HHs within the TAZ, AND 4) shareX100 of total District Employment within the TAZ
- MTC\_disaggregation\_nhb.csv - This file is used by the TP+ matrix module to disaggregate non-home based trips. This is similar to the previous file, except that the share of district level employment is used at both the production and the attraction side. In contains 4 fields: 1) District, 2) TAZ, 3) shareX100 of total District Employment within the TAZ, AND 4) shareX100 of total District Employment within the TAZ
- Allocate\_nhb.csv - This file is used by the the TP+ matrix model to disaggregate internal-SF non-home-based trips from the MTAZ level to the SFTAZ level. In

contains 4 fields: 1) MTAZ, 2) TAZ, 3) shareX100 of total MTAZ employment within the TAZ, and 4) shareX100 of total MTAZ employment within the TAZ.

- MTC\_disaggregation\_hbw.csv: This file is used to establish targets for nonSF resident workers working in SF TAZs, for use in the shadow pricing mechanism of the workplace destination choice model. It contains 4 fields: 1) County ID, 2) TAZ, 3) shareX100 of total county households within the TAZ, and 4) shareX100 of total county size within the TAZ. For creating this process, a special size term was estimated based on the different employment categories
- event.log – Contains informational messages logged by the software.

## **NETWORKS**

The CHAMP3 system uses two primary types of networks: roadway networks and transit networks. The San Francisco portions of the CHAMP3 roadway and transit networks were primarily developed in-house by SFCTA staff, based on the City's GIS basemap. The non-San Francisco portions of the CHAMP3 networks are based on MTC's regional Baycast model roadway and transit networks.

The San Francisco portions have been extensively reviewed and revised to simplify maintenance and more accurately reflect network conditions. On roadway side, only one input roadway network for each model horizon year is now required by CHAMP3 (FREEFLOW.NET). Time period specific information (such as the number of general purpose travel lanes and the number of buslanes by time-of-day) is now maintained using a link attribute for each time period, rather than maintaining separate networks for the AM peak, PM, peak and midday. Within San Francisco, the network link facility types, area types, turn penalties, and directional information were reviewed and revised as appropriate to best reflect network supply conditions.

Significant changes were also made to the San Francisco portions of the transit network. Most critically, MUNI travel speeds were linked to congested roadway travel times, which is described in a subsequent section. In addition, SFCTA staff updated all San Francisco transit route operating assumptions, such as alignments and frequency by time-of-day, for all model horizon years. Finally, changes were made to transit network coding conventions, such as the creation of separate rail rights-of-way in tunnels and where streetcars do not operate in mixed flow.

No changes were made to the non-San Francisco portions of the roadway network. These portions of the network are based directly on MTC's regional model roadway networks. In order to be integrated with the San Francisco GIS-based portions of the CHAMP3 networks, the regional MTC node numbers are increased by 1000.

In contrast, the regional transit networks were extensively revised to add transit route alignment and operating attributes by time-of-day and direction. The CHAMP3 model system uses five time periods, while the MTC's regional model transit networks are represented as simply peak and off-peak service. Using the regional model transit networks as a starting point, for each time period the SFCTA staff coded inbound and outbound route alignments and operating assumptions such as frequency and stop locations. Finally, the transit network route files were reorganized by operator, with time-of-day attributes coded by transit route. In the CHAMP2 transit networks, all routes and operators were combined to create five large transit route files organized by time-of-day. Changes to alignments and frequencies required the modification of up to five separate files. In the revised CHAMP3 transit network coding scheme, modification of a single transit route attributes requires changes only a single file.

### Linking Transit and Roadway Speeds

As part of the CHAMP3 model enhancements, a method for linking congested roadway speeds to transit speeds in mixed flow conditions was developed, implemented and validated. Establishing a linkage between roadway and transit speeds (and travel times)

ensures logical and behavioral consistency in the model components. Differences in travel times significantly influence the sensitivities of a number of CHAMP3 model components, especially the tour and trip mode choice models. With this linkage, as congestion increases and vehicles travel more slowly, transit vehicles operating in mixed flow also travel more slowly. This linkage establishes a consistent method for relating auto and transit speeds, and is based on a comparison of observed data on auto and transit speeds.

### Observed Auto Speeds

The observed data on auto speeds and travel times were derived from data collected in 2006 by the San Francisco County Transportation Authority on average travel times on the set of roadway segments identified as the Authority's Congestion Management Program network. This data is collected only during the AM and PM peak periods.

### Observed Transit Travel Times

The observed data on transit travel times were derived from AVL (Automatic Vehicle Locator) data provided by MUNI. In order to use MUNI's AVL data, it was first necessary to develop a software tool that calculated observed MUNI travel times by route and segment from the point-based AVL data. This tool reads in the geographic points of the AVL data and associates them with the nearest transit stop found in the CHAMP3 transit networks. The points are sorted chronologically, and the point-to-point travel times calculated. If a travel time cannot be calculated for a specific link, it is interpolated using the average travel speed for that route, allowing the speeds and travel times for any user-defined route segment to be calculated.

Because the AVL data does not reliably distinguish between the different routes, so the software determines the correct route through geographic analysis. In addition, the tool incorporates checks to filter out flawed data if there is too much time or distance between subsequent AVL points. These filters prevent excessive travel times when a bus is out of service, or excessive travel speeds if data from two

vehicles across town are adjacent. As outputs, the software tool reports the average runtime and other statistics for each link, route, and user-defined segment. This information, along with the CMP travel time data, was used to estimate the transit-roadway speed linkage.

### Roadway Transit Linkage

Linear regression was used to statistically estimate the relationship between observed transit travel time and a variety of related independent variables. The independent variables tested included the highway time, the distance, and the number of stops. The highway time and number of stops were segmented by facility type and by area type, but no meaningful differences were found based on those segmentations. The best results were obtained through constrained estimations, where one or more of the coefficients was first fixed.

The best initial bus analysis, combining estimated and asserted parameters, and which was subsequently adjusted in calibration was:

$$\begin{aligned} \text{Bus Time} &= 1.2 * \text{Highway Time in Mixed Flow} \\ &+ 1.0 * \text{Free-flow Time in Bus-Only Lanes} \\ &+ 0.44 * \text{Number of Stops} \end{aligned}$$

This model has a logical relationship between the variables. It implies that the Muni busses traveling in mixed flow are 20% slower than the roadway traffic on the same streets, and that each stop adds 26 seconds to the runtime. Where bus only lanes are present, busses travel at the posted speed limit.

Linking roadway speeds and travel times to MUNI rail speeds and travel times is more complicated, because some rail segments have completely separate rights-of-way, such as the Market Street subway, while other rail segments are in mixed flow. For the rail segments with separate right-of-way, the AVL observed travel time was

hard-coded in the transit networks. For the rail segments in mixed flow, a relationship between roadway and rail travel times and speeds, similar to that used for buses, was developed. In order to handle difficulty with co-linearity, the best results were obtained when the highway time coefficient was constrained to be consistent with the coefficient used for buses. As with buses, segmentation by facility type and area type did not improve the estimated results. The preferred model for rail lines operating on highway segments was:

$$\text{Rail Time} = 1.2 * \text{Highway Time in Mixed Flow} \\ + 0.35 * \text{Number of Stops}$$

This model implies that in mixed-flow rail vehicles travel at approximately the same speed as busses, but with less delay per stop. The rail vehicles have shorter stop times because they allow more passengers to board or alight at the same time.

The bus and rail equations shown above are used to calculate MUNI bus and rail travel on mixed-flow segments. In addition to addressing MUNI travel times and speeds, CHAMP3 was modified to also consider travel times and speed for other Bay Area transit operators providing service to San Francisco. The approach for regional operators involved applying the same set of relationships to all bus routes in the region. These stop time factors were then calibrated by mode to match the average travel time by mode.

In application, the transit skim-building and assignment TP+ scripts calculate a new roadway network field called BUSTIME, which is the highway travel time factored by the estimated highway time coefficients (1.0 \* highway time for links with bus-only lanes and 1.2 \* highway time for all other links). Representing the stop delay is more complicated because TP+ requires that stop delay be explicitly coded for each stop. An AWK script is used to automatically add the delay codes to the transit line files, and is integrated into the CHAMP3 transit network skimming and assignment procedures.

The relationships were calibrated by applying them in a base-year model, and comparing the travel time by route to the observed travel time by route. For the Muni routes with valid AVL data, the travel times from the AVL data processor were used as the observed values. For the non-Muni routes where the AVL data was not available, the RUNTIME values coded in the transit line files were treated as the observed/scheduled travel times.

Two changes were made to the application formulas during calibration. First, for freeways and expressways, the highway time factor was reduced from 1.2 to 1.0. This change was made because busses operating on freeways are less limited by the vehicles' acceleration and deceleration characteristics and more likely to operate with the flow of traffic. It also served to increase the speeds of the premium bus modes, which were previously observed to be too slow.

The second change made was that the stop time factors were adjusted to better fit the observed data. The initial estimated stop time factors were 0.44 for busses and 0.35 for rail. Table 2 and Table 3 show the final calibrated model coefficients. The non-Muni local bus routes tend to have slightly less stop delay than the Muni routes, and the premium bus routes have less stop delay than the local routes. These differences can probably be attributed to the volume of passengers boarding and alighting at each stop, or to the specific operating characteristics of the routes.

**Table 2: Final Highway Time Factors**

Roadway Type	Highway Time Factor
Freeway or Expressway	1.0
Arterial or Below	1.2
Facility with Bus Lane	1.0

**Table 3: Final Stop Time Factors**

Mode	Description	Stop Time
1	Muni Express Bus	0.50

2	Muni Local Bus	0.50
3	Light Rail	0.40
4	BART	0
5	Other Local Bus	0.50
6	Premium Bus	0.20
7	Premium Bus	0.20
8	Premium Bus	0.20
9	Premium Rail & Ferry	0

Table 4 shows a comparison of the modeled and observed runtimes on Muni routes. In the aggregate, the revised method for calculating transit runtimes better matches the observed runtimes than the original method. The overall root mean squared error is 17%. Table 5 shows the validation results comparing the scheduled and modeled runtimes for all transit routes. Modes 4 and 9 are BART and ferry/Caltrain modes that use hard-coded RUNTIMES, and thus have no difference. The overall percent root mean squared error is 26% for all routes.

**Table 4: Validation Results for Muni Routes**

Mode	# Routes	Observed Time			Modeled Time		Difference		% Difference		% RMSE	
		Min	Max	Avg	Orig	Rev	Orig	Rev	Orig	Rev	Orig	Rev
Muni Bus	157	32.3	60.9	43.8	38.3	44.4	-5.4	0.6	-12%	1%	21%	19%
Muni Rail	42	25.1	58.5	42.2	38.0	39.3	-4.2	-2.9	-10%	-7%	13%	11%
Total	209	30.3	60.6	43.5	38.3	42.9	-5.2	-0.5	-12%	-1%	19%	18%

**Table 5: Validation Results for All Routes**

Mode	Description	# Routes	Scheduled	Modeled	Difference	% Difference	% RMSE
			Runtime	Runtime			
1	Muni Express Bus	34	37.9	37.4	-0.5	-1.2%	2%
2	Muni Local Bus	414	52.9	52.9	0.1	0.1%	3%
3	Light Rail	108	31.2	30.4	-0.8	-2.6%	8%
4	BART	41	65.4	65.4	0.0	0.0%	0%
5	Other Local Bus	2697	41.8	41.9	0.1	0.2%	29%

7	Premium Bus	66	90.6	94.7	4.0	4.5%	28%
8	Premium Bus	125	46.2	50.4	4.2	9.2%	34%
9	Premium Rail & Ferry	114	58.1	58.1	0.0	0.0%	0%
Total		3644	44.8	45.1	0.2	0.6%	26%

## **SYNTHETIC POPULATION**

The disaggregate, tour-based structure of CHAMP3 predicts daily activity patterns and the demand for travel at the individual person-level. In order to operationalize this approach, it is necessary to first build a “synthetic population” of households and persons whose attributes, such as household size or the number of workers, match observed or expected patterns. A new population synthesizer was implemented in CHAMP3 that is significantly more sophisticated and comprehensive than that used in the previous version of the model. CHAMP3 uses the ARC (Atlanta Regional Council) population synthesis tool, adapted for application in the San Francisco and the Bay Area. This tool provides a great deal of flexibility in defining and validating population segments. The new population synthesizer incorporates a greater number of “controlled for” attributes than were included in the original population synthesizer, including the presence of children in households, housing type, and group quarters population.

The CHAMP3 population synthesizer first develops a “base year” population distribution using year 2000 Census data. A set of controlled for attributes are defined, and Census Summary File 1, Summary File 3, and the Census Transportation Planning Package information is used to develop single and multi-dimensional distributions of these attributes. In CHAMP3, these attributes include:

- Householder age
- Household size
- Household income
- Presence of children in household
- Number of workers in household
- Number of units in household structure
- Population race
- Population group quarters type

Once this distribution is established, the population synthesis tool then samples PUMS records to create a fully enumerated representation of the population.

In order to use the CHAMP3 to forecast the demand for future travel, it is necessary to develop future year synthetic populations. Because detailed future year distributions are not currently available, the base year distributions of household and person attributes are updated to provide future year distributions of these attributes, based on future year data found in MTC's regional model TAZ inputs and the SFCTA's CHAMP3 TAZ inputs. The CHAMP3 population synthesizer is applied at the CHAMP3 TAZ level for the entire Bay Area.

### Group Quarters Residents

Group quarters residents are treated as a separate category of households. In the PUMS data, each group quarters resident has a record in the person format as well as a record in the household format representing a one-person pseudo-household containing only that individual. These fields are distinguished from the normal household records by the UNITTYPE field, which indicates if the record is a household record, a non-institutional group quarters record, or an institutional group quarters record. This field is used to distinguish the type of household, and group quarters residents are otherwise treated just like any other household record. In the CHAMP3 implementation of the population synthesizer, institutional group quarters residents are generated by the model so that the total population matches the control totals, but because institutional residents are not expected to travel, these records are not printed to the population output file used by CHAMP3.

### Household Categories

Each household is grouped into household defined by eight dimensions. The dimensions are:

- Household unit type (3)
  - Household
  - Non-Institutional Group Quarters
  - Institutional Group Quarters;
- Income in 1999 dollars (4)
  - <\$30k
  - \$30-60k
  - \$60-100k

- \$100k+
- Householder age (2)
  - 0-64
  - 65+
- Household size (4)
  - 1
  - 2
  - 3
  - 4+
- Presence of own children age 0-17 (2)
  - Yes
  - No
- Number of Workers (2)
  - 0
  - 1
  - 2
  - 3+;
- Number of Units in Structure (2)
  - Single-Family Attached or Single-Family Detached
  - All Other
- Race (2):
  - White-Alone Non-Hispanic
  - Other.

A simple product of the number of categories in the eight dimensions indicates that up to 3,072 household categories would be possible. However, to keep the number of categories manageable, not all combinations are used. Combinations of the eight dimensions that are excluded or merged include:

- Illogical combinations of workers and household size are excluded
- Illogical combinations of presence of children and household size are excluded
- For households with a householder age 65+, no distinction is made between those households with or without children
- For group quarters, no distinctions are made by household income
- For group quarters, no distinction are made by household size
- For group quarters, no distinctions are made by presence of children
- For group quarters, no distinction is made by the number of units in the structure.

These rules limit the total number of categories to 592 for households and 16 for group quarters, totaling 608 mutually exclusive and collectively exhaustive categories.

### Control Totals

The 2000 PUMS data are tabulated into the categories above to generate a seed distribution with 8 dimensions and 608 cells. This seed distribution is then adjusted using iterative proportional fitting (IPF) to a set of marginal control totals for one or more of the dimensions. For the base-year application, those control totals are derived entirely from 2000 Census data tabulated at the block-group level and converted to a TAZ-level. The controls include households by:

- Householder Age x Household Size x Presence of Children ( $2 \times 2 \times 2 = 8$  controls);
- Household Size (4 controls);
- Household Income x Householder Age ( $4 \times 2 = 8$  controls);
- Household Size x Number of Workers ( $4 \times 4 = 16$  controls);
- Household Income x Household Size ( $4 \times 4 = 16$  controls);
- Household Income x Number of Workers ( $4 \times 4 = 16$  controls);
- Household Income x Household Size x Number of Workers ( $3 \times 4 \times 4 = 48$  controls);
- Household Size x Number of Units ( $4 \times 2 = 8$  controls);
- Number of Units (2 controls);
- Race (2 controls);
- Group Quarters Type x Householder Age ( $2 \times 2 = 4$  controls);
- Group Quarters Type x Number of Workers ( $2 \times 2 = 4$  controls); and
- Total households (1 control).

These dimensions add up to 119 individual controls ( $8 + 4 + 8 + 16 + 16 + 16 + 48 + 8 + 2 + 2 + 4 + 4 + 1 = 119$ ). When controlling to these base-year marginals, the IPF produces a floating point base-year seed distribution for the 608 categories. This new seed distribution is then adjusted through a second IPF process to match a set of “forecast-year” marginal control totals. While these control totals are labeled “forecast-year,” they represent totals

for any model year based on the subset of data available in the standard TAZ data files prepared by MTC for the regional BAYCAST model, and by the SFCTA for CHAMP3. For the forecast years, a more limited set of control totals is available in the TAZ data files. Multi-dimensional distributions are not directly available in the TAZ data files, and some attributes such as race are not present in the TAZ data files. The forecast-year control totals include households by:

- Household Size (4);
- Number of Units (2);
- Income (4);
- Number of Workers (4);
- Householder Age (2) x Presence of Children (2);
- Householder Age (2) for Group Quarters Residents; and
- Number of Workers (2) for Group Quarters Residents.

This second IPF process results in a floating point future-year seed distribution for the 608 categories. That distribution is then converted to an integer seed distribution using a randomized rounding method. The randomized rounding works such that if a cell contains the value 0.14, it has an 86% chance of being rounded to 0, and a 14% chance of being rounded to 1. This randomized rounding is preferred because it avoids bias, but it does not guarantee that the total number of households in a TAZ exactly matches the targets. Households are drawn from the PUMS sample to fill this integer distribution and create the synthetic population. Any income values less than zero are set to zero prior to writing the population.

### Household Submodels

The forecast-year control totals are based on the information found in the BAYCAST and CHAMP3 TAZ data files and in the Census data. However, prior to use in the population synthesizer, it is necessary to develop additional detail not represented directly in the TAZ data files. A set of seven household submodels were established to provide this detail, including:

- Income Inflation Submodel;
- Household Children Submodel;
- Householder Age Submodel;
- Group Quarters Age Submodel;
- Group Quarters Workers Submodel;
- Household Workers Submodel; and
- Household Size Submodel.

Income Inflation Submodel

The MTC ZMAST file breaks households into four income quartiles based on the household income in 1989 dollars. The 2000 Census data, however, reports household incomes in 1999 dollars. To account for this difference, the MTC breakpoints are inflated to 1999 dollars, which results in breakpoints that are close to, but not exactly the same as the income breakpoints in the 2000 census. Table 6 compares the MTC and Census income groups.

**Table 6: MTC and Census Income Groups**

	MTC Income Groups (1989 \$)		MTC Income Groups (1999 \$)		Census Income Groups (1999 \$)	
	Low	High	Low	High	Low	High
Quartile 1	\$ 0	\$ 25,000	\$ 0	\$ 33,589	\$ 0	\$ 30,000
Quartile 2	\$ 25,000	\$ 45,000	\$ 33,589	\$ 60,460	\$ 30,000	\$ 60,000
Quartile 3	\$ 45,000	\$ 75,000	\$ 60,460	\$ 100,766	\$ 60,000	\$ 100,000
Quartile 4	\$ 75,000	+	\$ 100,766	+	\$ 100,000	+

Because the MTC income groups in 1999 dollars do not perfectly align with the Census income groups in 1999 dollars, some households must be shifted between income groups to match the census breakpoints. The shifts are made using the percentages shown in Table 7. These percentages are calculated from the distribution of incomes found in the 2000 PUMS data. For example, of all households in the PUMS earning less than \$33,589, 14.1% earn at least \$30,000.

**Table 7: Household Income Quartile Shifts in Income Inflation Submodel**

Old Group	New Group	% of HH in Old to Shift to New
Quartile 1	Quartile 1	85.9%

Quartile 1	Quartile 2	14.1%
Quartile 2	Quartile 2	95.5%
Quartile 2	Quartile 3	4.5%
Quartile 3	Quartile 3	96.7%
Quartile 3	Quartile 4	3.3%
Quartile 4	Quartile 4	100.0%

When the synthetic population is written to disk, the incomes in the standard household file are by default written in 1999 dollars. However, to maintain consistency with the existing SF-CHAMP model, the household incomes written in the SF formatted output file are in 1989 dollars.

#### Household Children Submodel

The household children submodel adjusts the share of households with children based on changes in the age distribution of the population. For each TAZ, the percent of households with children found in the 2000 Census, and the age distribution found in the 2000 TAZ data file are stored as model inputs. When the submodel is applied, the age distribution in the application-year TAZ data file is compared to the base age distribution, and the share of households with children is adjusted proportionally to the change in the share of the population age 0-19. For example, consider a TAZ in which 10% of households in the base year have children, and 20% of the base-year population is age 0-19. If the share of the population age 0-19 increases to 24% in the future, the share of households with children will increase to 12%.

#### Householder Age Submodel

The household age submodel is similar in structure to the household children submodel. It increases the share of households with a householder age 65+ proportionally to the share of the population age 65+. While an MTC staff analysis of historic Census data did not reveal a clear pattern of this relationship, it is still deemed an appropriate assumption because it allows a mechanism for aging the population in the future.

#### Group Quarters Age Submodel

The group quarters age submodel changes the share of group quarters residents age 65+ proportionally to the change in the population age 65+. The total group quarters residents are calculated as the difference between total population and household population.

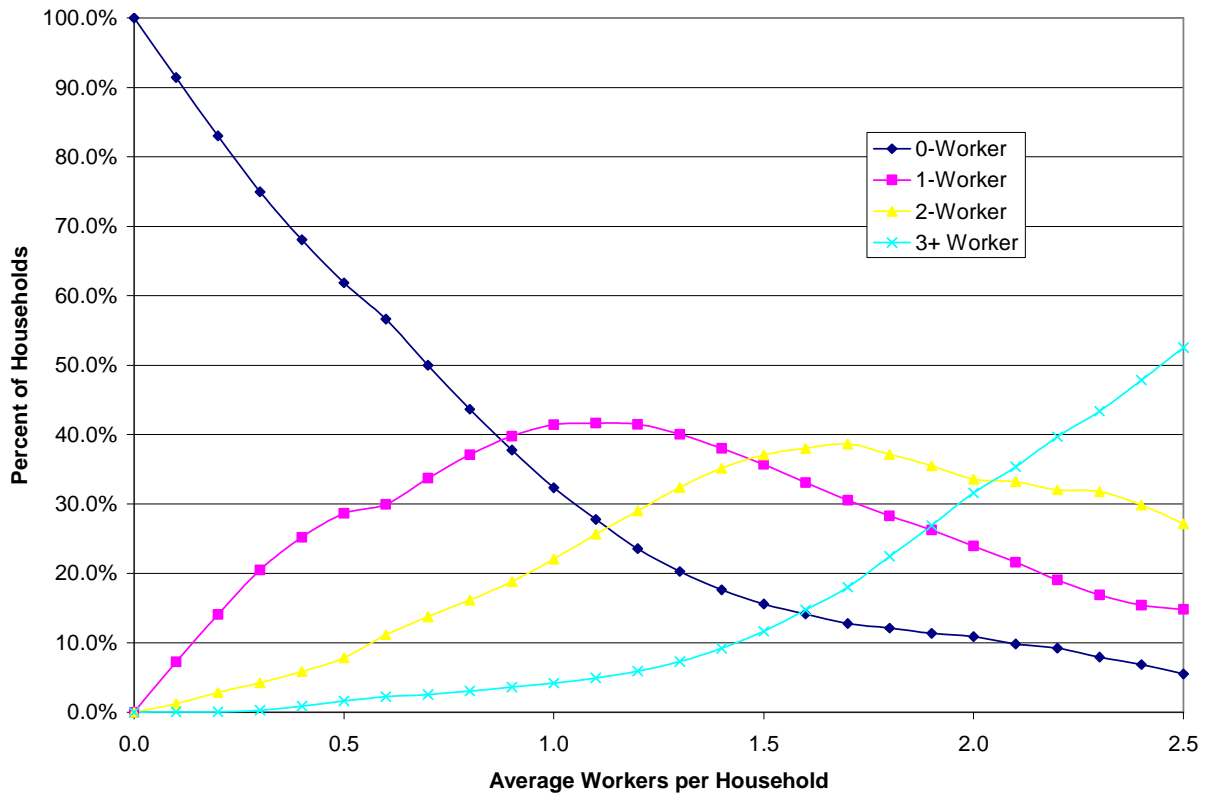

#### Group Quarters Workers Submodel

This submodel splits the total group quarters population in each TAZ into workers and non-workers, based on the share of group quarters residents in the base year who are workers. The base-year group-quarters workers are derived from Census Transportation Planning Package data by subtracting the workers in households tables from the total workers tables. After applying the group quarters workers submodel, the number of household workers in a TAZ can be calculated, allowing that variable to be used as the basis for the household workers submodel.

#### Household Workers Submodel

The household workers submodel is a proportional allocation model that converts the average number of workers per household to categories of households by number of workers. This conversion is made using a lookup table, which is shown graphically in Figure 9. The lookup table was created by relating the household categories to the average household size as found in the 2000 Census data at a block group level.

**Figure 9: Household Workers Submodel**

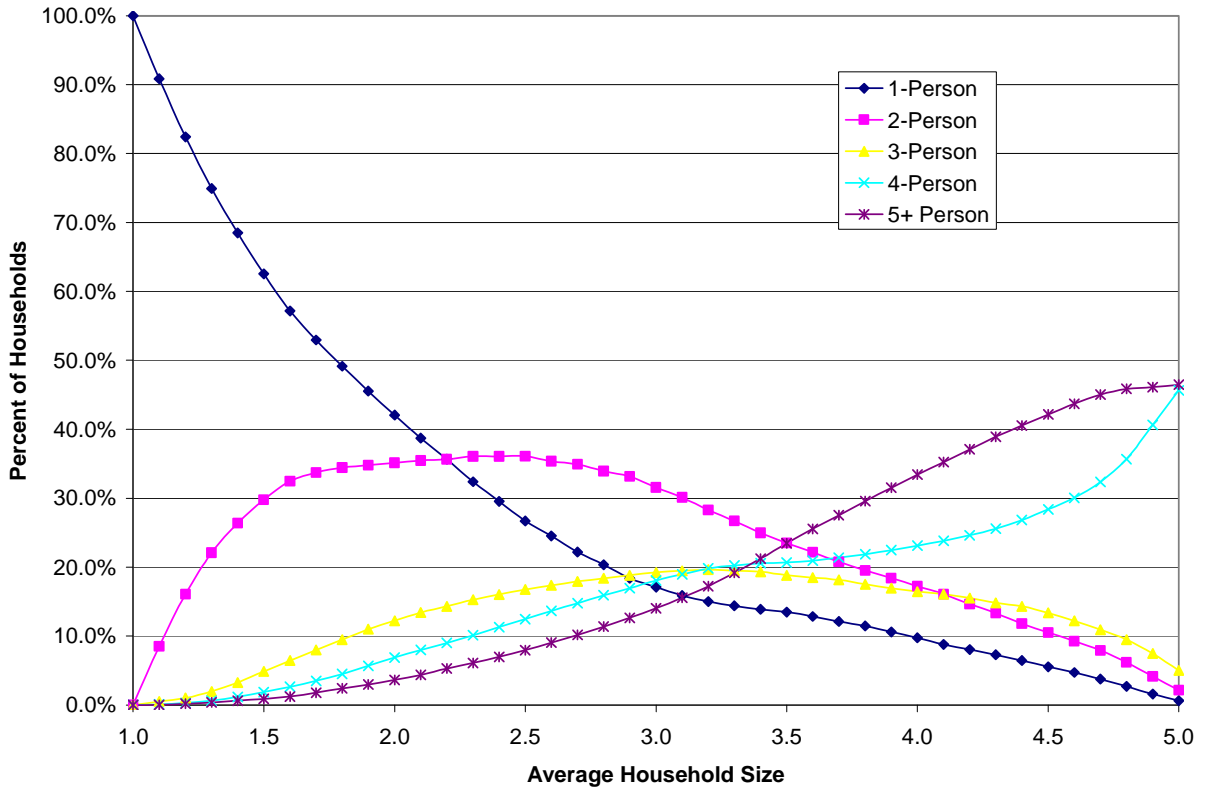

The household workers submodel allows for separate sets of curves for San Francisco County county and the rest of the Bay Area, though the current configuration of the population synthesizer uses the same curves for all areas. This implementation allows for additional flexibility in future calibration efforts.

### Household Size Submodel

The household size submodel is a proportional allocation model used to convert the average household size to the number of households grouped by size. It is graphically depicted in Figure 10.

**Figure 10: Household Size Submodel**

Like the household workers submodel, the household size submodel allows for a different set of curves for SF county and the rest of the Bay Area, though the current configuration of the population synthesizer uses the same curves for all areas. This implementation allows for additional flexibility in future calibration efforts.

Validation Results

The population synthesizer was implemented to generate populations representing residents of the entire Bay Area, though at present CHAMP3 only uses the synthetic population of San Francisco residents to forecast travel. Table 8 and Table 9 show the population synthesizer validation results for San Francisco County and for the 9-County area, respectively. The validation results compare the synthesized population to Census data or to the TAZ data at a PUMA level. All values are percents, unless the category label indicates that it is a total. Note that not all categories in the validation tables are controlled for, and it is expected that any controlled categories will fit better than the uncontrolled categories.

Overall, the synthesized population is 0.9% too high in San Francisco County, but 1.2% too low in the 9-County area. This discrepancy is due to the difference in the average sizes of 4+ person households, which are uncontrolled. The exact population can be calibrated by adjusting the curves in the household size submodel, but in order to match the values in both San Francisco County and the region as a whole it would be necessary to use two separate sets of curves.

**Table 8: Population Synthesizer PUMA-level Validation Results for San Francisco County**

Label	Pop Syn %	Census %	Mean Diff. %	Std. Dev. %	Min. Diff. %	Max. Diff. %

## ROADWAY ASSIGNMENT VOLUME DELAY FUNCTION REVISIONS

Prior to initiating the CHAMP3 model system updates, SFCTA staff reviewed and revised the parameters used in the roadway assignment procedures. This review was initiated after staff expressed concern that lower level facility types, such as local streets and collectors, were under-predicted in the base year. In addition, it was discovered that the model was not appropriately sensitive on these facilities to future roadway changes. To address these concerns, SFCTA developed a new set of assignment parameters. These parameters were further adjusted as part of the CHAMP3 development process to ensure that the resulting congested speeds and volumes were reasonably well calibrated in the base year.

Table 10 shows, by facility type, the original CHAMP2 and the revised CHAMP3 alpha and beta parameters, as well as the travel time adjustment factor used in calibration. The alpha parameters on freeway facility types was increased, which has the effect of making speeds decline more quickly as volumes increase, thus shifting more traffic onto non freeway facilities. In contrast, the alphas for lower level facilities were generally decreased, meaning that speeds do not decline as rapidly as congestion increases, thus increasing volumes on these facilities. The betas for the freeway facility types were adjusted only slightly, while the betas for the non-freeway facility types were reduced significantly, which results in speeds decline more gradually as congestion increases. The betas for local and collector streets were increased significantly, which results in speeds close to free-flow even as congestion increases and generally higher volumes on these facilities. However, once capacity is approached, speeds decline precipitously. Finally, a gamma factor is applied to the calculated congested link travel time in order to better match observed congested travel times.

**Table 10: CHAMP3 Roadway Traffic Assignment Parameters**

Facility Type Name	Facility Type ID	Alpha		Beta		Gamma	
		CHAMP2	CHAMP3	CHAMP2	CHAMP3	CHAMP2	CHAMP3
Freeway	2	0.88	0.83	6.0	5.5	1.0	1.0
Fwy-Fwy Connector	1	0.71	0.88	6.0	5.5	1.3	1.3

Local	11	0.71	0.60	6.0	8.5	1.3	1.8

## COMMERICAL / VERY SMALL TRUCK DEMAND

The CHAMP3 model system does not explicitly forecast commercial or truck trips. The model incorporates forecasts of truck demand prepared by MTC as part of the regional BAYCAST model system. Previously, this commercial and truck demand was based on MTC’s traditional truck trip tables, and augmented by factoring up a portion of non-home-based trips within San Francisco. Since the development of the original CHAMP model, MTC has modified their truck forecasting process to include a new segment representing daily commercial trips, such as taxis and light duty four-tire “very small” trucks. The new very small truck trip table has been incorporated into CHAMP3, and the factoring of non-home-based trips eliminated. The new “very small truck” trip tables are very significant in size, containing millions of trips.

In order to integrate these trips into CHAMP3, a set of time of day factors were developed based on observed roadway volumes. Table 11 shows these factors. In the overall CHAMP3 calibration and validation effort, described in subsequent sections, the very small truck demand was further adjusted to improve the roadway count validation effort by time-of-day, including increasing the overall volumes of these trips, and shifting these trip around by time of day.

**Table 11: Time-of-day Factors for Trucks**

Period	EA	AM	MD	PM	EV
--------	----	----	----	----	----

Factor	0.018	0.160	0.400	0.200	0.222
--------	-------	-------	-------	-------	-------

## EXTERNAL TRIPS

The CHAMP3 model system does not explicitly forecast external trips, that is, trips with at least one end outside of the nine Bay Area counties. Instead, the model incorporates forecasts of daily external trips prepared by MTC as part of the regional BAYCAST model system. No external trips were represented in the previous version of CHAMP.

In order to integrate these trips into CHAMP3, it was necessary to develop a set of factors by time-of-day and direction. These factors were based on Caltrans hourly count data at the external station locations collected between 2000 and 2005. Caltrans counts were not available for all external locations, so the final factors by time-of-day and direction are based on the combined results for available external station locations. Table 12 shows these factors.

**Table 12: Time-of-Day and Directional Factors for External Trips**

	EA	AM	MD	PM	EV
Inbound	0.0419	0.0991	0.1823	0.0915	0.0852
Outbound	0.0145	0.0564	0.1537	0.0932	0.1821

## INTEGRATING REGIONAL DEMAND

The CHAMP3 model system predicts the travel behavior of San Francisco residents traveling within San Francisco. Non-resident and inter-county forecasts of travel demand are derived from MTC's regional BAYCAST travel demand forecast model. MTC's regional model is an advanced 4-step travel demand model, which predicts peak and offpeak trips by purpose at a zone level approximately equivalent to census tracts. In contrast, CHAMP3 forecasts linked tours and trips across five time periods at a more detailed zone

level, approximately equivalent to Census block groups. Due to the different temporal and spatial resolutions and structures of these models, it is necessary to establish a process by which temporal and spatial detail is added to the regional MTC travel demand in order to integrate this demand with the more detail CHAMP2 demand.

#### Spatial Disaggregation of BAYCAST Trip Tables

The BAYCAST trip tables are disaggregated to the more detailed SF zone system using separate mechanisms for roadway and transit trips. First, total daily trips by purpose are calculated from the daily, peak, and off-peak trip tables. The roadway trips are then aggregated to nine districts within San Francisco and disaggregated to the SF zone system based on the each zone's share of the total district households or employment. This approach maintains the trip distribution at an aggregate level, but also ensures consistency of regional destinations with San Francisco TAZ-level employment. This aggregation / disaggregation process is implemented in a TP+ script using the MTC\_disaggregation.csv and MTC\_disaggregation\_nhb.csv files described earlier in the TAZ data processing section. The daily trips by purpose are then assigned time-of-day and directionality using a set of purpose and mode specific factors derived from MTC's 2000 Bay Area Travel Survey (2000BATS).

Transit trips are processed slightly differently than highway trips. Rather than first aggregating up to the district level and then disaggregating down to the TAZ level, transit trips are disaggregated directly from MTC TAZs to SF TAZs using the Allocate\_nhb.csv. This approach maintains the geographic detail of the MTC trip tables, which is more important for transit because a relatively small change in the destination can push a trip out of walking distance and result in transfer, significantly changing the assignment results. Separate peak and off-peak transit trip tables are maintained where available, and split directly from peak into AM and PM, and from off-peak into EA, MD, and EV. Maintaining consistency with MTC's peak period transit demand also ensures a greater consistency of the trip tables with the transit networks and improves the regional transit assignments.

#### Adjusting Disaggregated Regional Trip tables

After disaggregating the MTC trip tables by time period and TAZ, a portion of critical county-to-county movements are then adjusted to match observed roadway and transit volumes at county cordons by time period. Vehicle trips are factored to match volumes on the Golden Gate Bridge, Bay Bridge, and at the San Mateo County line. In addition to the county-cordon adjustments, intra-SF vehicle trips are also adjusted to ensure that the initial model skims reasonably match observed congestion levels. Similar to the roadway adjustments, transit person trips are adjusted to better match observed TransBay volumes and observed volumes at the San Mateo County line. Also, in an effort to better match the “through” volumes on BART, trips between San Mateo County and Alameda County are also adjusted. Table 13 shows the roadway adjustment factors, and Table 14 shows the transit adjustment factors.

**Table 13: Intercounty Roadway Adjustment Factors**

Location	Direction	Early AM	AM Peak	Midday	PM Peak	Evening
Bay Bridge	West	4.19	0.64	0.95	0.93	1.31
	East	1.37	0.99	0.82	0.63	1.58
Golden Gate	South	1.27	0.56	1.02	0.82	1.65
	North	1.55	1.34	1.25	0.73	1.34
San Mateo Countyline	North	1.23	1.05	0.87	0.86	1.62
	South	0.77	1.00	0.88	0.95	1.62
Intra-SF		2.24	0.95	1.08	0.98	1.49

**Table 14: Intercounty Transit Adjustment Factors**

Location	Direction	Early AM	AM Peak	Midday	PM Peak	Evening
Bay Bridge	West	-	0.555	2.101	1.272	2.897
	East	-	1.037	1.508	0.627	4.142
Golden Gate	South	-	0.533	1.419	0.542	1.849
	North	-	0.500	1.582	0.513	1.699
BART Thru	North/East	-	0.553	1.000	0.542	1.000
	South/West	-	0.500	1.000	0.513	1.000

Intra-County NHB Trips by Non-Residents

Ultimately, all intra-SF travel made by San Francisco residents is predicted by the CHAMP3 model. However, intra-SF non-home based travel made by non-SF residents are taken from the MTC model using a factoring process specific to the mode, time period, origin area type, and destination area type. The share of intra-SF trips person trips made by non-SF residents as derived from the MTC model was compared to the share of intra-SF trips by non-residents reflected in the household survey. The non-resident trip tables were adjusted by time period to match the observed shares in the survey. The shares and totals of intra-SF trips by non-SF residents are shown in Table 15. To avoid an excess of non-resident transit trips, only the highway trips are scaled.

**Table 15: Shares and Total Intra-SF Trips by Non-SF Residents**

Time Period	Share of I-I Trips by Non-Residents		Modeled I-I Trips
	Observed	Modeled	by Non-Residents
EA	10%	9%	2,347
AM	6%	7%	34,375
MD	19%	21%	270,855
PM	13%	13%	87,673
EV	9%	9%	60,852
Total	13%	14%	456,102

## CORE BEHAVIORAL MODEL COMPONENT UPDATES

The “core” model components of model system include separate models for predicting individual and household choices of auto ownership, tour generation, time-of-day, tour destination and mode choice and trip destination and mode choices. Each model component was evaluated and revised to reflect revisions to the model structure and recalibrated to reflect the latest observed data.

The primary source of observed data used to revise and recalibrate the core model components was the 2000 Bay Area Travel Survey (BATS2000). The BATS2000 is a detailed household travel survey, containing information on individual and household travel

behavior for over 15,000 Bay Area households. The BATS2000 data was supplemented by the additional household travel diaries collected by the BART using an identical survey instrument and collected in 2000 and 2001. The household surveys were expanded to represent the households and individuals for the entire region using a multi-dimensional expansion scheme that considered household income, household size, household workers, household autos, and neighborhood. Finally, an on-board survey of MUNI riders collected in 2004 was used to support the mode choice and transit assignment calibration efforts.

## **WORKPLACE LOCATION CHOICE**

The first of the core behavioral models applied in CHAMP3 is the workplace location choice model. Applying this model at the beginning of the model stream allows the information on workplace location to be used in subsequent models such as the auto ownership. This model predicts the primary workplace location for workers, and is applied regardless of whether the subsequent daily activity pattern model predicts that a work tour was made during the simulated day. If a work tour is predicted, then the workplace location is identified as the work tour destination. The workplace location choice model is shadow priced to ensure that each job is filled by one worker, within a 5% threshold at a TAZ level. Considerable effort was spent in model calibration due to the model's influence on subsequent models, and also because of the importance of the work commute market to transit forecasts.

### Allocation of Non-Resident Workers

CHAMP3 predicts the travel-related choices of San Francisco residents, but also must consider the travel choices of non-San Francisco residents. In order to forecast where San Francisco residents choose to work, the model system must consider how many San Francisco residents work in other Bay Area counties, as well as how many non-SF residents work in San Francisco, and where specifically in San Francisco they commute to. A key feature of CHAMP3 is that workplace destination choice is "shadow priced," so that the combined number of San Francisco and non-San Francisco resident workplace destinations

to any given TAZ is approximately equal to the number of jobs in that TAZ. The fixed non-SF resident workplace destinations in San Francisco, derived from MTC trip tables, is first allocated to San Francisco zones. Non-residents “consume” some of the jobs in each TAZ, and the remaining employment establishes a target through which shadow-pricing can allocate these jobs to San Francisco residents.

The method for allocating non-SF resident workers to San Francisco job locations was revised in CHAMP3. In order to predict where in San Francisco non-residents work, a regression model was estimated to determine the share of jobs in each TAZ filled by non-workers, using the employment by type as the descriptive variables. This regression model provides a measure for each TAZ of the attractiveness of the TAZ for work destinations for non-SF residents. For each TAZ, this measure, or attractiveness index, is then converted into a relative share of citywide attractive, which is then applied to the number of non-SF residents working in San Francisco. This estimates the number of non-SF residents working in each TAZ, which is then used in shadow pricing to set the target number of SF residents that work in each TAZ. This equation is fully documented previously, in the section describing the TAZ data processor.

### Destination Choice Sampling

The sampling mechanism used in the workplace destination choice model, as well as the other destination choice models, was also revised in CHAMP3 in order to be more consistent with discrete choice theory. Sampling of alternatives is commonly used in destination choice models so as to avoid needing to compute a complicated utility equation for a large number of alternatives, where many of the alternatives may have very low probabilities of being selected. Instead, it is possible to define a “simple” utility equation that has a user-specified size term and a user-defined dispersion parameter on distance between zones.

$$U_{ij} = \ln(S_j) - \text{lambda} * \text{dist}_{ij}$$

where **lambda** is typically (1 / average observed trip length)

This utility is then used in a multinomial logit model to determine the probability that the destination will be chosen for the sample set. Because the variables are not specific to the employee/traveler, the probabilities can be calculated once at the beginning of the model run. The sample is chosen with replacement proportional to the probabilities. Sampling correction factors are calculated and are returned along with the sample set. These correction factors are then added to the “full” utility that is used in the choice model for selecting an alternative from the sample set.

$$CF_{ij} = \ln(\text{freq. of } j \text{ in sample set} / (\text{sample size} * \text{probability of } j \text{ being in set}))$$

where **probability** was calculated from applying the MNL model to the above utility

This sampling strategy was implemented in the work destination choice and other destination choice models. However, it was observed during model calibration that while this sampling approach worked very well for the vast majority of trips, it resulted in too few alternatives being included in the sample that were very far from the home TAZ, producing an under-prediction of trips from San Francisco to Santa Clara County. To resolve this issue, the negative exponential distribution was modified such that after a critical distance, the distribution became uniform, or flat. In CHAMP3, this means that all destinations beyond 25 miles had a probability of being selected that is proportional to their size term alone.

### Calibration

Calibration of the workplace location choice model focused on matching the following observed data:

- Trip length frequency distributions from the household survey;
- Neighborhood to Neighborhood worker flows from the Census;
- Intrazonal trip rates;
- Share of workers in each district that are non-residents; and
- Area type to Area type worker flows from the Census.

As previously mentioned, a shadow pricing is a key features of the workplace destination choice model, though the imposition of shadow pricing constraints has implications for the calibration process, and requires that all model inputs are as consistent and accurate as possible. Significant effort was spent adjusting the base year employment data and building a model to predict the work locations of non-SF residents, as discussed in earlier sections of this document. In addition, it was necessary to establish a rate (1.307) to apply to non-home-based trips in order to estimate the number of these trips destined to workplace locations.

The previous version of the CHAMP workplace destination choice model included a number of “dummy” variables applied to specific categories of trips or specific combinations of origins and destinations. For the CHAMP3 recalibration, some of these coefficients were calibrated to better match observed data, while in other cases these dummy variables were deemed irrelevant, and their coefficients were zeroed out. Specifically:

- The average household income coefficient was set to zero because it was not logical;
- Area type destination flags were set to zero because have no effect when shadow pricing is implemented,
- The intrazonal constant was calibrated,
- Area type to Area type constants were calibrated,
- County destination constants were calibrated.

Note that the dummy variables are not necessarily mutually exclusive. For example, Alameda County has a flag for itself, but is also included in a more general East Bay term.

The piece-wise linear distance coefficients were calibrated to correct for an under-prediction of very short trips. Finally, the model was modified to use a higher mode choice logsum coefficient (0.300 instead of 0.0921), making the model more sensitive to travel time. This value was selected based on experience in other regions. The final model coefficients are shown in Table 16.

## VEHICLE AVAILABILITY / AUTO OWNERSHIP

The vehicle availability (also known as the auto ownership model) predicts the number of vehicles each household chooses to maintain and which are available for use by household members. Given the location of the household, the characteristics of household members, and the primary workplace location of each work, the model estimates the probability of a household having 0, 1, or 2+ vehicles. The model was originally estimated using the 1990 Bay Area Travel Survey. No changes were made to the structure of the vehicle availability Model

### Calibration

Calibration of the vehicle availability model focused on matching the number of observed households but vehicle availability class (0 vehicles, 1 vehicles, 2+ vehicles) and by:

- MTC Superdistrict
- Household Income

- Number of Workers in the Household

**Table 21: Calibrated Workplace Destination Choice Model Coefficients**

Coefficient	Original Values			Final Values		
	1veh	2veh	3veh	1veh	2veh	3veh

## TOUR GENERATION & TIME-OF-DAY

The tour generation and time-of-day models in CHAMP3 predict the purpose, number, types, and timing of tours and trips made by individuals during the day. Calibration targets derived from BATS2000, excluding additional BART sample. Expansion based on San Francisco residents.

Although the models were not re-estimated, a number of changes affecting the structure and the sensitivities to the model were made. These changes included addition of more detailed school tour purposes, new person types to accommodate new school purposes, and adjustments to the accessibility measures included in the model.

Changes made in calibration included – changing the school tour rate?

### School Purpose Segmentation

The most significant structural change to the tour and trip generation model was the more detailed segmentation of the school purpose. The changes were made primarily to ensure that grade school student school tour destinations were attracted to TAZs containing grade school enrollment, high school tour destinations were destined to TAZs with high school enrollment, and college tours were destined to TAZs with college enrollment. SFCTA staff developed detailed estimates of enrollment in both public and private schools for all TAZs within San Francisco. For areas outside San Francisco, MTC's estimates of college enrollment were used (San Francisco resident grade school and high school students are assumed to attend schools within San Francisco County).

### Updated Person Type Definitions

In order to support this more detailed school tour generation scheme, it was necessary to update the definitions person types used in CHAMP3. In previous versions of CHAMP, there were four basic person types:

- Child (<16),
- Adult worker (16+ employed full or part time OR primary tour work),
- Adult student (16+ attend school full or part time OR primary tour school),
- Other adult (Everyone else 16+).

In CHAMP3, the person types definitions are now:

- Child (<16, and People age 16-20 who are still enrolled in high school),
- Adult worker (21+ and employed regardless of whether or not they also go to school),
- Adult student (anyone 16-20 and enrolled in college, anyone 21+ who is a student and not employed).
- Other adult (21+ unemployed)

Under this person type scheme, most full time college students will get school patterns with possible secondary work tours, while part time students who also work will get work patterns with possible secondary school tours. All secondary tours are called "other" within the model.

The structure of the non-school tour purpose models were unchanged.

#### Accessibility Measure Adjustments

Another significant set of changes to the CHAMP3 tour generation models involved making adjustments to the sensitivity to the accessibility measures used in the model. These measures allow the number of tours generated and the number of intermediate stops on tours to be influenced by the proximity to desired destinations. The measures reflect the amount of total employment and retail / service employment within certain time and distance thresholds as measured from both home and work locations. Accessibility measures used in the CHAMP model system include:

- Adult workers
  - o Employment w/I 15 minutes by car from home in PM peak
  - o Retail & Service w/I 15 minutes by car from home in PM peak
  - o Retail & Service w/I ½ mile of home
  - o Retail & Service w/I ½ mile of work
  - o Retail & Service w/I 15 minutes by car from home in offpeak
- Students / Children
  - o Retail & Service w/I 15 minutes by car from home in PM peak
- Other Adults
  - o Retail & Service w/I 15 minutes by car from home in offpeak
  - o Retail & Service w/I ½ mile of home

These parameters on accessibility were revisited because SFCTA and PB staff discovered that the model appeared to be oversensitive to changes in these measures in application. An investigation of the elasticities of tour and trip generation with respect to accessibility was performed, and elasticities as high 0.5 (for other tours made by workers) were identified. Although one would expect workers making other tours to be sensitive to changes in accessibility, due to the fact that the proximity of home to a greater number of destinations would likely increase home-based other tours and reduce intermediate stops on work tours (as this investigation also illustrated), the demonstrated elasticity appeared too strong.

In order to address the perceived oversensitivity of the model to the accessibility measures, the coefficients for adult workers on auto travel time-based accessibility measures were scaled by 0.25. No changes were made to the child, student, or other adult models, and no changes were made to the coefficients on employment within a ½ mile. The changes produced an elasticity of about 0.15 for workers making other tours (previously 0.48), and 0.04 overall (previously 0.14).

One significant limitation of the current accessibility measures used in CHAMP3 are that they are primarily based on changes in auto travel time. In model applications where transit capacity is increased and roadway capacity is reduced (and thus accessibility to destination by roadway reduced), tour and trip-making may actually decline. A future improvement to the model's sensitivity to changes in accessibility would be the incorporation of multimodal logsum-based impedance measure, rather than roadway impedance based measures.

### Calibration

The tour generation model works in conjunction with the time-of-day models. The time-of-day models predict the timing of the outbound and return legs of each tour, as well as the timing of the individual trips that comprise the tour. In conjunction with the roadway validation effort, some tours were shifted by time of day in order to better match observed roadway volumes. Specifically, some other purpose tours were shifted to later in the day with evening period return times, while the share of other purpose tours occurring entirely within the AM peak was reduced. In addition, a small number of work tours were shifted from the early AM to the AM peak time period. Table 22 compares the expanded household survey to the estimated trips by tour purpose, person type and time of day. Table 23 compares these same statistics for the previous and revised versions of the model.

## NON-WORK TOUR DESTINATION CHOICE

The tour destination choice models predict the primary destinations for tours. Each tour purpose (work, grade school, high school, college, other, work-based) has a unique tour destination choice model. As previously described, the first of the models to be run is the workplace destination choice model, which is run at the beginning of the model system so that the model system is sensitive to the influence of work location choice on the number of autos owned, the number and types of tours generated and time-of-day choices. If the tour generation model predicts that a worker will make a work tour, then the chosen workplace location becomes the destination for this tour. The primary tour destinations for the other

tour purposes are predicted after the tour generation and time-of-day model has established each individual's daily activity pattern.

In addition to the changes made to the workplace destination choice model describer earlier in this document, a number of structural changes were also made to the non-work tour primary destination choice models. These changes included revisions to the sampling mechanism, segmentation of the school model into three school type models, and modifications to the specification of size terms.

### Destination Choice Sampling

The sampling mechanism implemented in the CHAMP3 workplace destination choice model was also implemented in the Grade School, High School, College, Other, and Work-Based tour destination models in order to be more consistent with discrete choice theory. Sampling of alternatives is used in destination choice models to avoid needing to compute a complicated utility equation for a large number of alternatives, where many of the alternatives may have very low probabilities of being selected. As in the workplace destination choice models, a “simple” utility equation was defined that has a user-specified size term and a user-defined dispersion parameter on distance between zones, and which is then used in a multinomial logit model to determine the probability that the destination will be chosen for the sample set.

### School Purpose Segmentation

The tour generation section of this document describes how the school purpose was segmented in CHAMP3 into three separate school markets: Grade School, High School, and College. The ability of the tour generation model to predict separate school purposes greatly enhances the ability of the school tour primary destination model to connect students with school destinations appropriate to their age. The SFCTA staff developed San Francisco TAZ-level estimates of public and private school enrollment for grade school, high school, and college and professional schools, which are used in CHAMP3 as size terms to attract

appropriately aged students. In addition, constraints were implemented so that for each school segment only TAZs with enrollment in the appropriate age school were included in the choice set; for example, grade school trips are destined only to TAZs with grade school enrollment. However, unlike the work purpose, shadow pricing of school destinations was not implemented.

### Size Term Specification

The third structural change to the primary destination choice models involved improvements to the specification of the size terms. In previous versions of the CHAMP non-work destination choice models, the probability of selecting a zone was proportional to the log of the size of that zone, where size is usually a measure of some combination of employment by sector. This specification is inconsistent with travel behavior theory, which asserts that the probability of selecting a TAZ should be directly proportional to the size of the TAZ, not to the log of the size of the TAZ. For example, doubling employment in a zone should, all other things being equal, double the number of trips attracted to that zone. The result of this specification error was that the previous model was under-predicting the number of trips to large attractors. In order to address this issue, it was necessary to estimate new parameters for the other tour destination and work-based tour destination models, using simple regression.

Estimate of new size term coefficients was performed using household travel behavior derived from the BATS2000 and BART add-on surveys and using CHAMP3 TAZ-level employment data. An estimation file was created from this data by summing expanded tour destinations by purpose to a district level. For purposes of estimation, the 26 neighborhood district system was used for destinations within San Francisco County. The MTC Super-District system was used for destinations outside San Francisco County. However, estimations at this level of geography were generally unsuccessful, probably due to the very large size of super-districts.

Table 24 shows the final estimation results for Other purpose tours. The estimation data relies on Other purpose tours made by San Francisco BATS2000 and BART households with destinations within San Francisco County. Based on this regression, retail employment tends to attract more other purpose tours than service employment, all else being equal. There is also a large coefficient on medical employment (note that the service variable also includes medical employment, for a total medical employment parameter of  $0.2686 + .9439 = 1.2125$ ), and coefficients on both number of households and grade school enrollment (Other tours include pickup/dropoff trips). The fit of the model is very good, with an adjusted R-squared of 0.9016. Note that in application all of the parameters are related to the retail parameter for consistency with logit theory, which requires that one less coefficient than total size function variables can be estimated.

**Table 24: Other Tour Destination Choice Size Term Estimation Results**

<b>Summary Statistics</b>			
R-squared	0.9205		
Adj R-squared	0.9016		
<b>Variable</b>	<b>Coefficient Estimated</b>	<b>Coefficient In Size Term</b>	<b>T-statistic</b>
Service Employment	0.2686	0.7836	1.37
Medical Employment	0.9439	2.7540	1.46
Retail Employment	0.3427	1.0000	1.12
Households	0.5670	1.6544	2.81
Grade School Enrollment	0.3435	1.0022	0.40

Table 25 shows the final estimation results for work-based tours. There are coefficients only on the retail and MIPS (Management, Information, and Professional Services) employment categories. The coefficient on retail employment is slightly higher than the parameter on MIPS employment. The relatively high MIPS parameter probably reflects work-related travel made to and from the regular workplace for work purposes. The fit of the model is good, with an adjusted R-squared of 0.9653.

**Table 25: Work-Based Tour Destination Choice Size Term Estimation Results**

<b>Summary Statistics</b>			
R-squared	0.9680		
Adj R-squared	0.9653		
<b>Variable</b>	<b>Coefficient Estimated</b>	<b>Coefficient In Size Term</b>	<b>T-statistic</b>
MIPS Employment	0.0634	0.7740	10.25
Retail Employment	0.0820	1.0000	2.57

In the CHAMP3 model system, the employment sectors used in San Francisco County are based on the City Planning Department’s land use classifications, and are different than the employment sectors used in non-San Francisco counties, which are derived from ABAG and MTC information. Model estimations were tested using employment differentiated by destinations within San Francisco versus outside San Francisco, but these estimations produced counterintuitive results, such as service employment being seven times more attractive than retail employment for non-SF counties. As a result, similar size terms were used for both San Francisco and non-San Francisco destinations, with the following modifications:

- For Other tours, no medical employment totals are available for non-SF zones.
- For Work-Based tours, service employment was substituted for MIPS employment for non-SF zones.

### Calibration

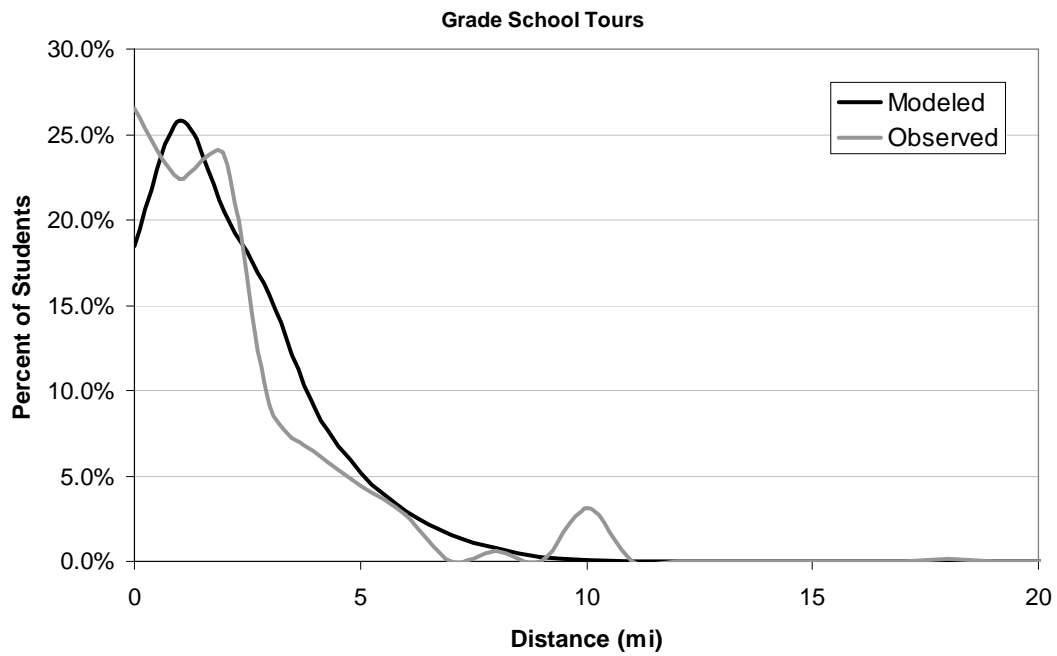

After making the structural changes to the model described above, the tour destination choice models were calibrated. The calibration effort focused on the following areas:

- The San Francisco destination constants were calibrated to properly match the number of tours with destinations within the county, versus external to the county.
- The piece-wise linear distance terms were adjusted to better match observed trip length distributions. Generally, this involved making the terms much steeper in the 0-2 mile range to get enough very short trips.
- The intrazonal constants were calibrated to match observed intrazonal trip rates.

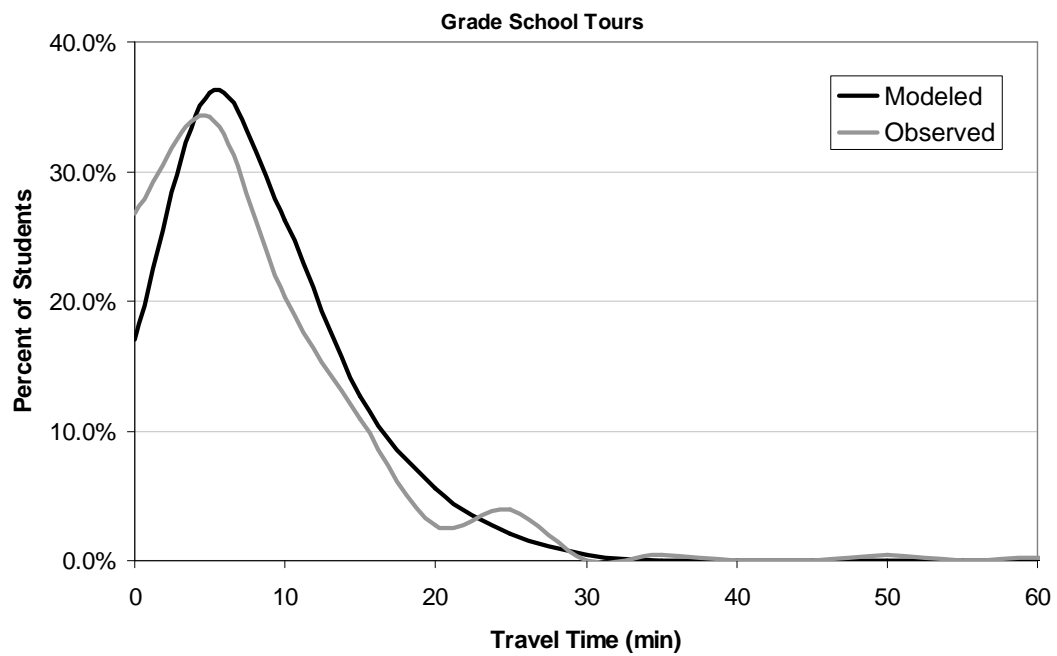

- The area type to area type constants in most cases, as most were found to contribute only marginally to improving the fit of the models compared to observed data.

Figure 14 through Figure 19 illustrates the calibrated distance and time trip length frequency distributions for each of the new school segments. The fit for each of the school segments was reasonably good, though the observed distributions for college tours were somewhat noisy, making calibration more difficult.

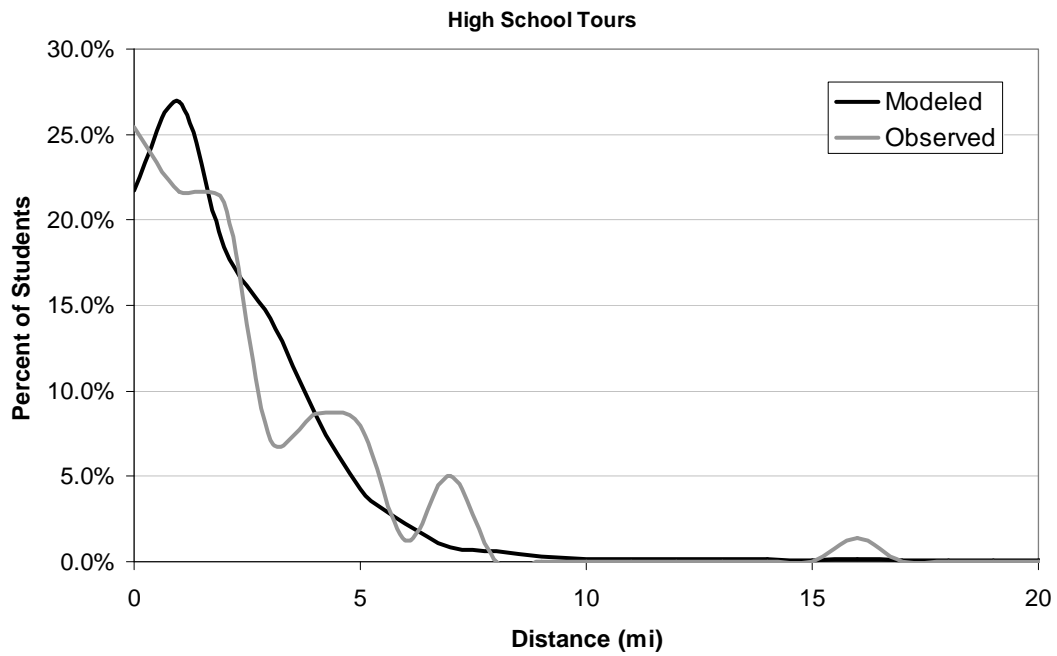

**Figure 14: Grade School Tour Length Frequency Distribution (Distance)**

**Figure 15: Grade School Tour Length Frequency Distribution (Time)**

**Figure 16: High School Tour Length Frequency Distribution (Distance)**

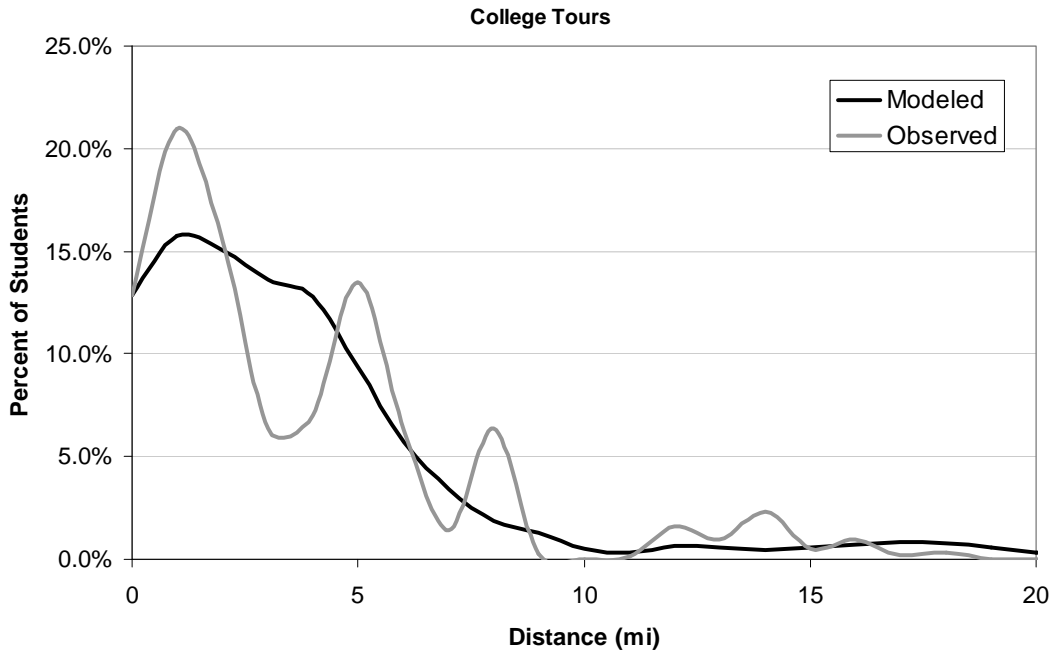

**Figure 17: High School Tour Length Frequency Distribution (Time)**

**Figure 18: College Tour Length Frequency Distribution (Distance)**

**Figure 19: College Tour Length Frequency Distribution (Time)**

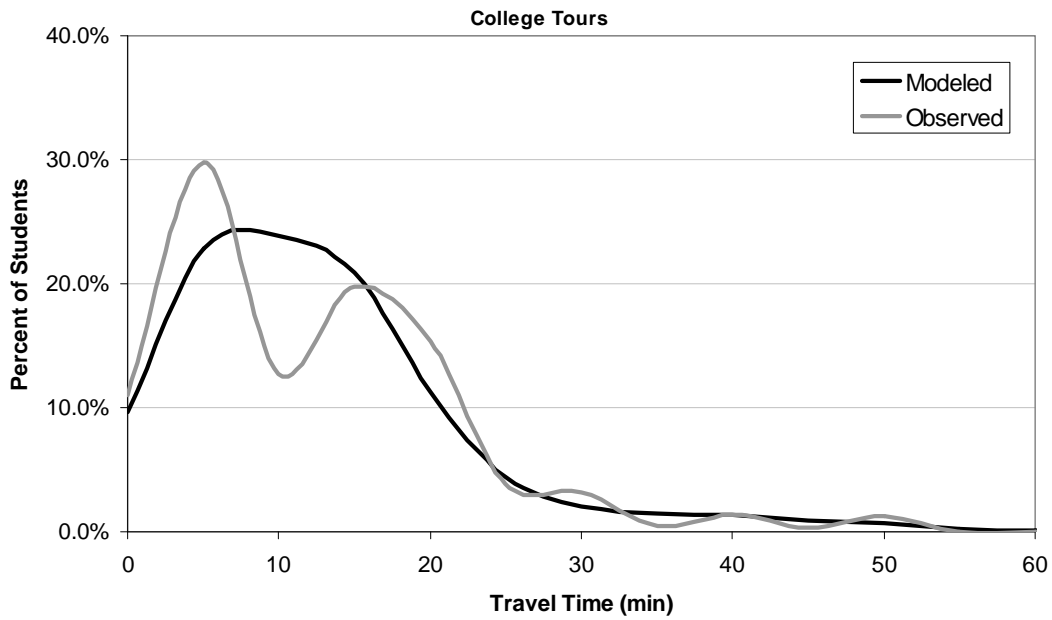

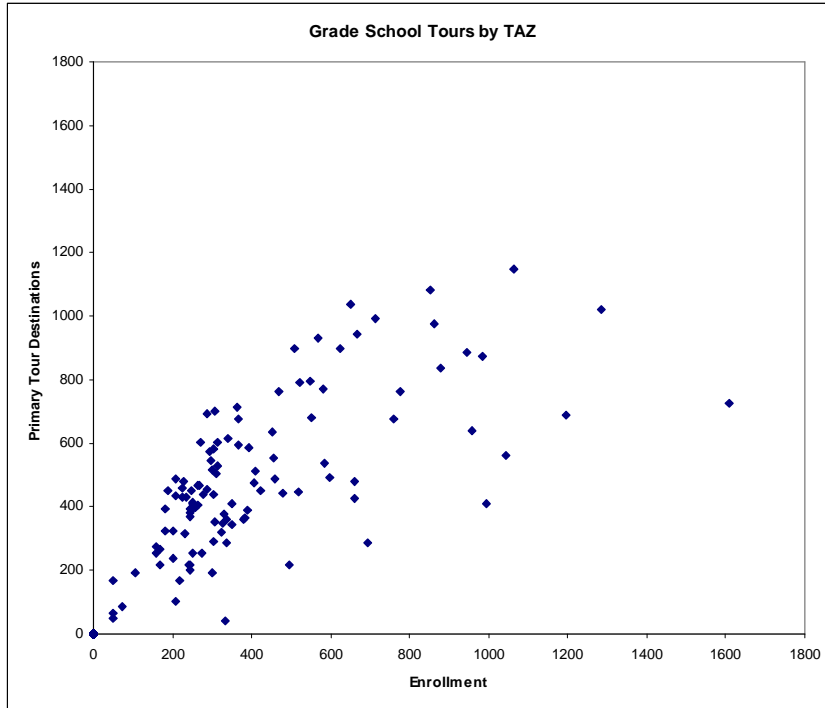

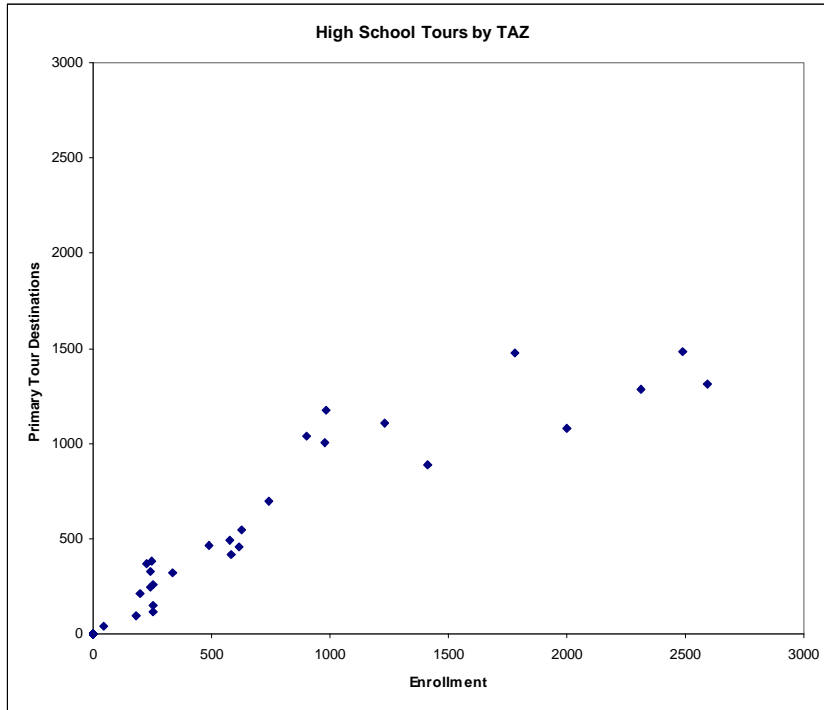

Figure 20 through Figure 22 illustrate the number of school destinations to school enrollment by TAZ. The figures demonstrate that the destinations are proportional to the

enrollment, as expected. The college tours show significantly fewer destinations than enrollment, probably due to the number of part-time students, and the commuters from outside SF. Also, as previously noted, unlike the work purpose, shadow pricing of school destinations was not implemented, meaning that the number of school destinations is not required to match enrollment within a given tolerance.

**Figure 20: Grade School Destinations vs. Grade School Enrollment by TAZ**

**Figure 21: High School Destinations vs. High School Enrollment by TAZ**

**Figure 22: College Destinations vs. College Enrollment by TAZ**

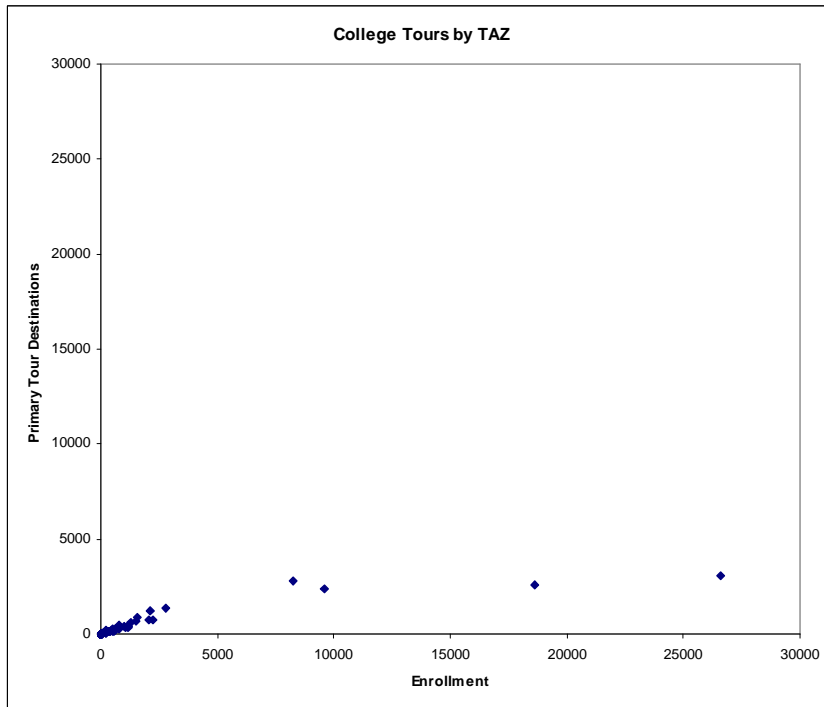

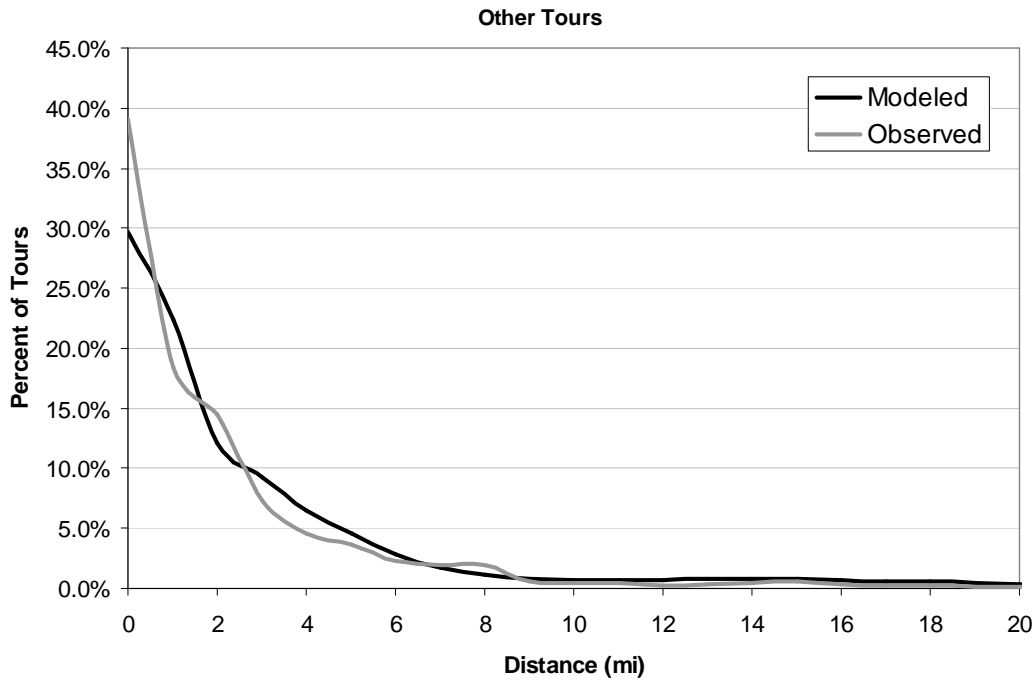

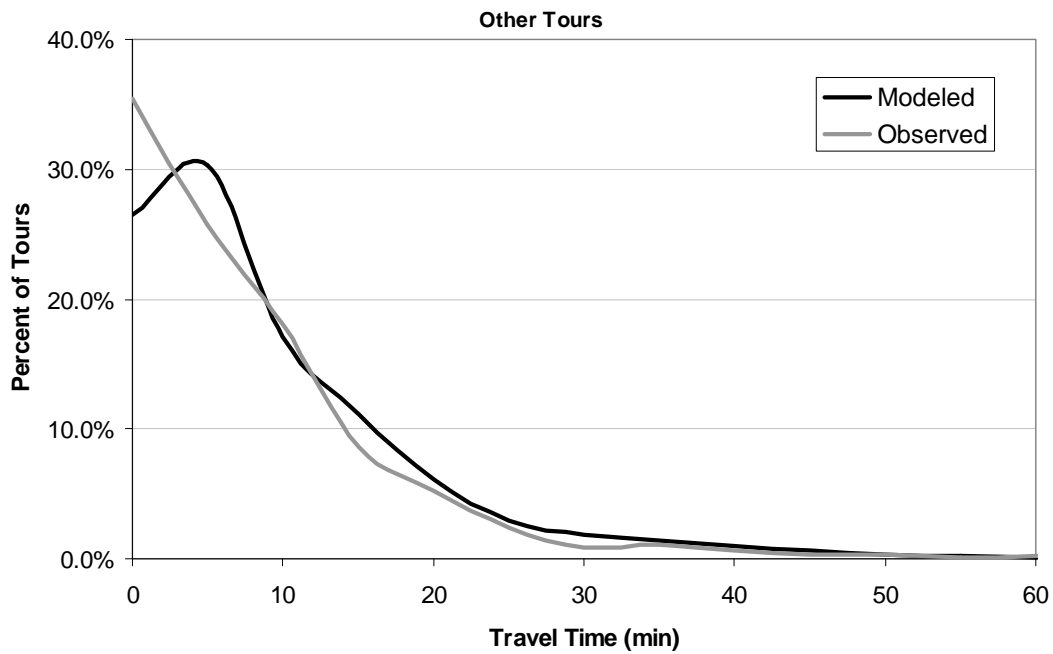

Figure 23 through Figure 26 demonstrates the final calibrated time and distance trip length frequency distributions for the other and work-based tour destination choice models.

## TOUR MODE CHOICE

The tour mode choice models predict the primary mode used for tours. Each tour purpose (Work, Grade School, High School, College, Other, Work-Based) has a unique tour mode

choice model. The modes available in the tour mode choice model include Driver, Passenger, Walk-Transit, Drive-Transit, Bike and Walk. The only structural change made to the tour mode choice models was the segmentation of the School tour mode choice model into separate Grade School, High School, and College tour mode choice models. The individual purpose tour mode choice models are further segmented by auto sufficiency, with three market segments in each model:

- Household autos = 0
- Household autos < household workers
- Household autos >= household workers.

For School tours, the zero auto and low auto markets are combined due to the relatively small sample sizes in each. The calibration involved adjusting the constants in each of these market segments to match the observed mode shares.

### Calibration

Calibration of each purpose-specific tour mode choice models involved making adjustments to alternative specific constants for each mode by market segment, in order to match observed modal shares. Three data sources were used to establish the observed modal shares: the BATS2000 household survey, the 2004 MUNI onboard transit survey, and counts of the observed transit ridership. These data sources were reconciled using the following approach:

- The tours in the expanded BATS2000 household survey were tabulated by purpose, market segment and mode. For work tours, these tabulations were compared to the 2000 Census Journey to Work data as a check on their validity.
- The zero auto and low auto market segments were combined for all of the School purpose tours.
- Because Drive-Transit is not permitted for non-work tours, any observed Drive-Transit tours were re-coded as Walk-Transit tours in the same purpose.
- Because Auto Driver is not allowed in the zero auto market segment, or in the Grade School purpose, any observations in this category were recoded as Auto Passenger tours.

- The tours were scaled to match the total number of tours that the model produces by purpose and market segment.
- To avoid constants converging to negative infinity, modes with zero observations were coded with a small number of tours.
- Because the trip mode choice models, which are conditional on the tour mode choice models, only allow Drive-Premium and Drive- BART, the number of Drive-Transit tours were scaled to remove the Drive-Local and Drive-Muni tours.
- The MUNI onboard survey was tabulated, and where the household and onboard survey diverged, the transit trips were adjusted to be more consistent with the onboard survey.

To calibrate the models, the alternatives specific constants were adjusted such that the modeled tours by mode matched the target values. Consideration was given to ensuring that the alternative specific constants change logically across market segments. To be more consistent with the trip mode choice models, a constant equivalent to 5 minutes of in-vehicle time is added to paths that include Muni Metro (LRT), and a constant equivalent to 10 minutes of in-vehicle time is added to paths that include BART. The structure of the tour-based CHAMP3 model requires that the tour mode choice models are calibrated first and then the trip mode choice models are calibrated, as the trip mode choices are conditional on tour mode choices. The calibration of both tour and trip mode choice models involved an iterative process of making to adjustments to each model.

## Results

Table 29 through Table 34 summarizes the final tour mode choice model calibration results for each of the tour purposes Table 35 through Table 38 shows the final calibrated model coefficients and constants.

**Table 29: Work Tour Mode Choice Calibration Results**

<b>MODE</b>	<b>Observed Share</b>	<b>Estimated Tours</b>	<b>Estimated Share</b>	<b>Difference</b>

## **INTERMEDIATE STOP CHOICE**

The intermediate stop choice models predict the location of stops made on the way to or from the tour primary destination. Up to eight intermediate stops (four on each half-tour) may be made on each tour. Each tour purpose has a unique intermediation stop choice model, though the specific purpose of the activity at the intermediate stop location are not predicted by the model.

A number of structural changes were also made to the intermediate stop choice models, similar to those made to the tour destination choice models. These changes included revisions to the sampling mechanism, segmentation of the School model into three school type models, modifications to the specification of size terms, and inclusion of a term on out-of-direction distance.

### Destination Choice Sampling

Sampling of alternatives is used in destination choice models to avoid needing to compute a complicated utility equation for a large number of alternatives, where many of the alternatives may have very low probabilities of being selected. The sampling mechanism for the intermediate stop choice models was updated in a manner similar to the updated sampling mechanism implemented in the tour primary destination choice models, with two key distinctions.

First, when intermediate stops are chosen two tour anchor points, rather than one, are known because both origin and destination have been established. Therefore, the alternatives for the intermediate stop models are drawn from two separate sampling distributions, one anchored at the tour's home location (or work for work-based tours), and one anchored at

the tour's destination. The correction factors are adjusted to account for this double-ended sample.

Second, when the intermediate stops are chosen the tour mode has also been established, so the intermediate stop locations samples are mode-specific. For example, for Walk and Bike tours, only TAZs within walking or biking distance are sampled. For Walk-Transit tours, only TAZs that can be accessed via transit or walk are sampled. For Drive-Transit tours, TAZs are sampled that can be accessed via transit or via auto at the production end are sampled. An additional improvement to the model related to the sampling and selection of alternatives is that "out-of-direction travel time" used as an impedance measure is calculated is mode-specific, rather than as the using roadway travel time for all modes, as was done previously.

#### School Purpose Segmentation

The tour generation section of this document describes how the school purpose was segmented in CHAMP3 into three separate school markets: Grade School, High School, and College. The ability of the tour generation model to predict separate school purposes greatly enhances the ability of the school tour primary destination model to connect students with school destinations appropriate to their age. The intermediate stop choice model carries forward the segmentation of school purposes added to the tour generation, tour primary destination and tour mode choice models.

#### Size Term Specification

The third structural change to the intermediate stop choice models involved improvements to the specification of the size terms, similar to the improvements made to the tour primary destination choice models. In previous versions of CHAMP intermediate stop choice models, the probability of selecting a zone was proportional to the log of the size of that zone, where size is usually a measure of some combination of employment by sector. As previously described, this specification is inconsistent with travel behavior theory, which asserts that the probability of selecting a TAZ should be directly proportional to the size of the TAZ. In the previous version of CHAMP, the size terms in the intermediate stop models

suffered the same problem as the size terms in the other primary destination choice models—they tended to under-predict trips to large attractors. The size terms were re-structured and re-estimated to allow for direct proportionality between the size of the zone and the probability of choosing the zone, all other things being equal.

The new size terms were estimated using data from the BATS 2000 household survey and CHAMP3 year 2000 TAZ land use data. An estimation file was created from this data by summing expanded tour intermediate stop destinations by tour purpose at a district level. For purposes of estimation, the 26 neighborhood district system was used for destinations within San Francisco county. The estimation process was constrained to consider only intermediate stop destinations within San Francisco County, as the intermediate stop destination choice models only consider intra-county destinations. Models were estimated for each tour purpose (Work, Grade School, High School, College, Other, and Work-Based).

Table 39 shows the final estimation results for Work tours. Retail employment tends to attract more Work tours than service employment, all else being equal. There are also coefficients on the number of households and grade school enrollment (stops to/from work often include dropoffs and/or pickups of children at school). The fit of the model is good, with an adjusted R-squared of 0.9206. In order to be consistent with logit theory in application, where there must be one less coefficient than total size function variables, the included size parameters are scaled to the retail parameter.

**Table 39: Work Tour Intermediate Stop Choice Size Term Estimation Results**

<b>Summary Statistics</b>			
R-squared	0.9328		
Adj R-squared	0.9206		
<b>Variable</b>	<b>Coefficient Estimated</b>	<b>Coefficient In Size Term</b>	<b>T-statistic</b>
Service Employment	0.1825	0.1801	1.45
Retail Employment	1.0135	1.0000	5.07
Households	0.2544	0.2510	2.25
Grade School Enrollment	0.8762	0.0865	0.26

Table 40 shows the final estimation results for Grade School tours. The final coefficients are limited to households, grade school and high school enrollment. No parameters on employment measures significant, reflecting the low probability of children making stops for shopping or other purposes on the way to or from school. The parameters on grade school and high school enrollment can be explained by two behavioral factors; first, they may reflect the propensity of school children to participate at sporting events and other activities at other schools; second, intermediate stops include pickups and dropoffs at school, and households with multiple children may be linking escort stops for more than one child per tour. The fit of the model is not as good as other intermediate stop models, but adequate with an adjusted R-squared of 0.5120. In order to be consistent with logit theory in application, where there must be one less coefficient than total size function variables, the included size parameters are scaled to the grade school enrollment parameter.

**Table 40: Grade School Tour Intermediate Stop Choice Size Term Results**

<b>Summary Statistics</b>			
R-squared	0.5683		
Adj R-squared	0.5120		
<b>Variable</b>	<b>Coefficient Estimated</b>	<b>Coefficient In Size Term</b>	<b>T-statistic</b>
Households	0.0017	0.0110	0.16
Grade School Enrollment	0.1533	1.0000	1.85
High School Enrollment	0.8268	0.5394	0.91

Table 41 shows the final estimation results for High School tours. Unlike the Grade School model, a positive parameter was estimated on retail employment. In addition, parameters were estimated on households, grade school, and high school enrollment. The fit of the model is also not as good as other intermediate stop models, with an adjusted R-squared of 0.3723. In order to be consistent with logit theory in application, where there must be one

less coefficient than total size function variables, the included size parameters are scaled to the high school enrollment parameter.

**Table 41: High School Tour Intermediate Stop Choice Size Term Results**

<b>Summary Statistics</b>			
R-squared	0.4689		
Adj R-squared	0.3723		
<b>Variable</b>	<b>Coefficient Estimated</b>	<b>Coefficient In Size Term</b>	<b>T-statistic</b>
Retail Employment	0.0050	0.0990	0.44
Households	0.0044	0.0871	0.63
Grade School Enrollment	0.0134	0.2653	0.34
High School Enrollment	0.0507	1.0000	1.15

Table 42 shows the final estimation results for College tours. The model includes parameters on retail and service employment, as well as number of households. The service employment parameter is higher than the retail parameter, perhaps indicating that shopping trips are less likely on College Tours (potentially due to less disposable income among college students). Parameter estimates on other variables were inappropriately signed. The fit of the model is good, with an adjusted R-Squared of 0.8133.

**Table 42: College Tour Intermediate Stop Choice Size Term Results**

<b>Summary Statistics</b>			
R-squared	0.8348		
Adj R-squared	0.8133		
<b>Variable</b>	<b>Coefficient Estimated</b>	<b>Coefficient In Size Term</b>	<b>T-statistic</b>
Service Employment	0.0686	2.1553	4.61
Retail Employment	0.0318	1.000	1.41
Households	0.0030	0.0945	0.35

Table 43 shows the final estimation results for Other tours. The model includes parameters on retail and service employment, medical employment, and number of households. Parameter estimates on other variables were inappropriately signed. The fit of the model is good, with an adjusted R-Squared of 0.8788. In order to be consistent with logit theory in application, where there must be one less coefficient than total size function variables, the included size parameters are scaled to the retail parameter.

**Table 43: Other Tour Intermediate Stop Choice Size Term Results**

<b>Summary Statistics</b>			
R-squared	0.8975		
Adj R-squared	0.8788		
<b>Variable</b>	<b>Coefficient Estimated</b>	<b>Coefficient In Size Term</b>	<b>T-statistic</b>
Service Employment	0.0772	0.4134	0.59
Medical Employment	0.6177	3.3053	1.47
Retail Employment	0.1869	1.0000	0.95
Households	0.4041	2.1624	4.59

Table 44 shows the final estimation results for work-based tours. The model has only one parameter, on retail employment. Parameter estimates on other variables were inappropriately signed. The fit of the model is high, with an adjusted R-Squared of 0.8788. In order to be consistent with logit theory in application, where there must be one less coefficient than total size function variables, the included size parameters are scaled to the retail parameter.

**Table 44: Work-based Tour Intermediate Stop Choice Size Term Results**

<b>Summary Statistics</b>

Adj R-squared	0.8285		
<b>Variable</b>	<b>Coefficient Estimated</b>	<b>Coefficient In Size Term</b>	<b>T-statistic</b>

Retail Employment	0.0936	1.0000	11.25
-------------------	--------	--------	-------

### Calibration

After making the structural changes to the model described above, the intermediate stop choice models were calibrated. The calibration effort focused on the following areas:

- The San Francisco destination flag variable was calibrated to properly match the number of stops within the city boundaries.
- The distance term was adjusted to match the total observed out-of-direction distance per tour.
- The intra-zonal constants were calibrated to match the observed intrazonal shares
- The area type to area type constants were zeroed out because they contributed little to the calibration.

### Results

Table 45 and Table 46 provides summary comparisons of average observed and estimated total tour distance and time by tour purpose. Figure 27 through Figure 32 shows the observed and estimated total tour distance (including intermediate stops) trip length frequency distributions. Finally, Table 47 through Table 50 show the original CHAMP2 and the revised CHAMP3 model coefficients for each purpose.

## TRIP MODE CHOICE

The tour mode choice models predict the mode used for the individual trip segments that comprise the tours. Each tour purpose (Work, Grade School, High School, College, Other, Work-Based) has a unique tour mode choice model. The modes available in the tour mode choice model include Drive-alone, Shared-ride 2, Shared-ride 3+, Walk-local bus, Walk-Muni Metro, Walk-premium regional transit, Walk-BART, Drive-“premium” regional transit, Drive-BART, Bike, and Walk. Two primary structural changes to the trip mode choice models were made. The School trip mode choice model was segmented into separate Grade School, High School, and College models, and premium transit modes were allowed where they had previously been prohibited.

### Calibration

The trip mode choice model predicts the mode for each individual trip conditional on the primary mode chosen for the tour. The goal of calibration was to obtain reasonable alternative-specific constants for each available trip mode within a tour mode, segmented by purpose. Particular attention was given to the transit modes, with the desire that the Muni and BART modes have a moderate and reasonable (0-20 minutes) preference over the local bus mode due to the higher level of reliability expected from exclusive guideway systems.

Three data sources were used to establish the observed modal shares: the BATS2000 household survey, the 2004 MUNI onboard transit survey, and counts of the observed transit ridership. These data sources were reconciled using the following approach:

- For each purpose, the trips in the expanded household survey were tabulated by trip mode and tour mode.
- Tour modes not available for a specific purpose were re-coded to the nearest tour mode. This included re-coding Drive- transit tours as Walk-transit for non-work purposes, re-coding Drive-transit tours to Walk-transit if the trip mode is Local bus or Muni (which do not allow Drive-transit), and recoding Auto Driver to Passenger for Grade School tours.

- Trip modes not available for a specific tour mode were re-coded to the nearest trip mode. This included re-coding Drive Alone trips to Shared Ride 2, where Drive Alone is not available, and re-coding Bike trips to Walk where Bike is not available.
- Cells that are available, but had zero observations, were given a small number of trips to avoid constants of negative infinity.
- The totals were scaled to match the total number of trips predicted by the model.
- These household survey based results were compared to the expanded trips by sub-mode and purpose in the onboard transit survey. Adjustments were made to make the targets more consistent with the onboard survey. This process also considered the number of trips by sub-mode required to match the observed transit boarding counts.

The alternative-specific constants in the trip mode choice models were adjusted to match these calibration target values. The final model coefficients are shown in Table 57 through Table 60.

## Results

Table 51 through Table 56 shows the trip mode choice results compared to the targets.

## ROADWAY & TRANSIT ASSIGNMENT CALIBRATION

Once the core behavioral model components were reasonably well calibrated, the refreshed CHAMP3 model system was applied, and the resulting travel demand assigned to the roadway and transit networks for validation of the entire model system. The roadway and transit assignment results were compared to observed roadway and traffic counts, and adjustments made to both the core behavioral components and to the regional demand derived from MTC's Baycast model. The observed roadway counts were based on a database of approximately 1,100 direction counts. The observed transit volumes were based on MUNI ridership data, augmented by information derived from the recent MUNI on-board survey. In addition to validating volumes, the estimated roadway speeds were also compared to observed speed data collected by the SFCTA as part of the Congestion Management Program.

### Roadway Calibration

The initial roadway assignment results under-predicted total roadway volumes by approximately 15%, primarily in the off-peak periods. The AM and PM peaks were within about 5%, the mid-day was about 15% low, and the evening was about 25% low. In order to address this under-prediction, the calibration effort focused on identifying the sources of this issue, and on iteratively revising the core model components and the regional demand adjustment procedures until a better match between estimated and observed volumes was achieved.

The following changes were made as part of this calibration process:

- The tour generation models were modified to produce more other tours, particularly secondary tours in the evening, and fewer other purpose tours during the peaks. The changes accounted for the expected under-reporting of off-peak in the household survey.
- The tour generation model was modified to produce more school tours.
- The work time-of-day model was adjusted to produce fewer tours in the early AM.

- The intra-SF non-home based auto trips were scaled to match the correct share of person trips in the city made by non-residents, based on shares derived from in the household survey.
- The factors applied to the MTC trip tables were calibrated match the observed inter-county screenline volumes.
- The commercial vehicle trip table was scaled up by 40%.
- The commercial vehicle time-of-day factors were adjusted to produce more trips in the mid-day and evening.

### Roadway Results

Table 61 shows the final validated volumes by facility type. Facility type refers to the type of roadway and is used in the model system to assign default roadway speeds and capacities. These general speeds and capacities, as well as the facility types assigned to individual links, may be adjusted as part of the calibration process. This table shows that all facility types except collectors and locals are well validated with relatively low %RMSE and estimated/observed ratios close to 1.00. Collectors are under-predicted by 23%, and local streets are under-predicted by 31%. SFCTA staff spent a considerable amount of time adjusting the default parameters for these facility types, and though still not perfect, these final assignment results for these facility types represents an distinct improvement over earlier versions of CHAMP (which underestimated volumes on collectors and locals by 35% and 46%, respectively).

**Table 61: Roadway Daily Volume Validation by Facility Type**

<b>Facility Type</b>	<b>Observed</b>	<b>Estimated</b>	<b>Est/Obs</b>	<b>%RMSE</b>
Interchange to Interchange	136,066	152,208	1.119	24%
Freeway	1,676,705	1,825,488	1.089	12%
Rural Arterial	71,567	77,508	1.083	38%
Collector	1,113,520	857,011	0.770	80%
Ramp	983,454	1,132,519	1.152	49%
Major Arterial	4,611,349	4,437,633	0.962	39%
Local	342,577	235,830	0.688	73%
Minor Arterial	1,749,780	1,857,329	1.061	57%
Arterial Plus	1,234,894	1,078,950	0.874	36%
<b>Total</b>	<b>11,919,912</b>	<b>11,654,475</b>	<b>0.978</b>	<b>45%</b>

Table 62 presents a summary of estimated and observed volumes by time-of-day. All time periods are well-validated, with the peak periods estimated within 2%, the midday and evening within 3%, and the early A.M. within 5%.

**Table 62: Roadway Daily Volume Validation by Time-of-Day**

<b>Time Period</b>	<b>Observed</b>	<b>Estimated</b>	<b>Est/Obs</b>	<b>%RMSE</b>
Early AM	297,607	282,280	0.949	120%
AM Peak	1,977,114	1,968,444	0.996	50%
Midday	4,341,930	4,223,357	0.973	48%
PM Peak	2,538,509	2,496,019	0.983	47%
Evening	2,764,752	2,684,375	0.971	56%
<b>Total</b>	<b>11,919,912</b>	<b>11,654,475</b>	<b>0.978</b>	<b>45%</b>

Table 63 and Table 64 summarize the AM. Peak and P.M. Peak roadway speed validation. Observed data on roadway speeds was available only for the peak periods. These tables show that all facility types, with the exception of rural arterials (in both time periods) and ramps (in the A.M. Peak) are very well validated, typically close to 10% different or less. The two problematic facility types comprise a very small portion of the total observed data, and the ramps

**Table 63: Roadway AM Peak Speed Validation**

Local	15	15	-1%
Minor Arterial	13	15	15%
Superarterial	20	18	-11%

### Transit Calibration

The transit assignment results are composed of two components—those trips made by San Francisco residents internal to the city, as predicted by the CHAMP3 model, and the regional inter-county demand, which is derived from the MTC model. Local transit demand can be changed through adjustments to the core CHAMP3 model components, specifically the tour and trip mode choice models. In contrast, regional transit demand is relatively fixed in that MTC’s regional trip distribution and mode choice models are not typically rerun as part of CHAMP3. Because the final transit forecasts arise from the combination of local and regional demand, each segment was considered independently as well as in conjunction with the other. The ability to consider local and regional transit demand separately was greatly enhanced by the availability of the recent MUNI onboard survey. The onboard survey contained critical information not available at the time of the original CHAMP model development, such as the share of non-San Francisco residents riding on MUNI buses or on MUNI Metro, or observed average transfer rates by MUNI sub-mode.

The most significant change made to the transit skimming and assignment process was the reduction of the weights on perceived in-vehicle travel times in path-building. The transit assignment process is hierarchical in structure, in that only certain modes are available to travelers, based on their mode choices. For example, if a traveler’s predicted mode is local bus, then only bus routes are available. However, if a traveler’s predicted mode is Muni Metro, then both bus and Metro rail routes are available. In previous versions of CHAMP, in order to ensure that the chosen mode was actually used by the traveler, the perceived in-vehicle travel time of the chosen mode was assigned a weight of 0.2 in path-building, meaning it was perceived to be very fast. In CHAMP3 this weighting scheme has been significantly reduced so that the preferred mode is only perceived to be slightly faster than the other modes. This modification was made because it leads to a more restrictive set of paths being given to the trip mode choice models, resulting in more reasonable trip mode choice constants on rail modes such as Muni Metro and BART. It is also consistent with FTA guidance.

A significant portion of the calibration was also focused on ensuring that regional, non-San Francisco resident demand is assigned to the proper transit sub-modes. The following steps were taken in calibrating the transit assignment models:

- The regional trip tables were factored such that the assigned transit volumes at count-cordon lines matched observed volumes at those locations.
- To mitigate an under-assignment of inter-county movements on premium busses, the premium bus in-vehicle time was weighted at 0.8 times the BART in-vehicle time.
- The initial assignments found that too many regional transit trips were transferring to the Muni busses and the Muni Metro. To avoid forced transfers, the maximum walk access and egress distances were increased from 0.5 miles to 1.0 miles for the regional transit modes (BART and Premium).
- To further mitigate the over-assignment of regional transit trips on the Muni system, transfers between regional transit and Muni busses or rail were given a 10 minute penalty, and the Muni busses and rail in-vehicle time was weighted at 1.2.

These changes are applied only to the regional transit assignment scripts, which used the fixed trip tables, not to the SF transit assignments.

### Transit Results

Table 65 presents a summary of MUNI boardings by sub-mode. Total MUNI ridership is validated to within 1% of year 2000 counts. Local and express buses are slightly under-predicted, and MUNI Metro and cable cars are slightly over-predicted.

**Table 65: MUNI Boardings by Submode**

<b>Mode</b>	<b>Observed</b>	<b>Modeled</b>	<b>% Diff</b>
Local Bus	531,878	520,838	-2%
Express Bus	29,176	28,692	-2%
Light Rail & CC	191,322	194,230	2%
Total	752,376	743,760	-1%

Table 66 presents a summary of MUNI boardings by time of day. This table shows the Early AM, AM peak, and evenings over-predicted, and the Midday and PM peak under-predicted. Caution should be used when interpreting these results because MUNI was

unable to provide detailed counts by time of day, and the onboard survey data by time-of-day proved to be unreliable.

**Table 66: MUNI Boardings by Time of Day**

Time of Day	Observed	Modeled	Difference
Early AM	4,209	5,186	23%
AM Peak	153,139	203,035	33%
Midday	306,049	230,338	-25%
PM Peak	206,628	185,387	-10%
Evening	82,352	119,814	45%
Total	752,376	743,760	-1%

As previously described, significant attention was paid to ensuring that the share of SF residents and regional travelers using MUNI bus and rail was reasonable and consistent with on-board survey data. Table 67 shows the distribution of boardings by MUNI submode and by residency status. Table 68 contains a MUNI route-level summary of year 2000 observed and estimated daily boardings. Figure 33 is a scatterplot that illustrates route-level observed and estimated daily boardings.

**Table 67: MUNI Boardings by Residency Status and Submode**

Submode	Residency Status	Observed	Modeled	Difference
Bus	SF Resident	510,559	499,145	-2%
	Non Resident	50,495	50,385	-0%
Rail	SF Resident	157,458	149,527	-5%
	Non Resident	33,864	44,703	32%
Total	SF Resident	668,017	648,672	-3%
	Non Resident	84,359	95,088	13%

**Figure 33: Scatterplot of Estimated and Observed MUNI Boardings by Route**

**Daily Boardings by Route**

Table 69 and Table 70 summarizes BART boardings by San Francisco station and time of day respectively. Daily BART boardings are underestimated by 2%, with the downtown stations being slightly overestimated, and the outlying stations being under-predicted. Estimated BART boardings by time-of-day match observed data closely, typically differing by about 5%.

**Table 69: BART Daily Boardings by San Francisco Station**

Station	Observed	Modeled	Difference
Embarcadero	31,114	29,269	-6%
Montgomery Street	31,634	37,398	18%
Powell Street	26,580	28,301	6%

## Land Use Inputs to SF-CHAMP model

# SAN FRANCISCO PLANNING DEPARTMENT

**MEMO**

**DATE:** July 3, 2013

**TO:** Elizabeth Sall, SFCTA  
Michael Schwartz, SFCTA

**FROM:** Aksel Olsen   
Information and Analysis Group

**RE:** Land Use Assumptions for the Van Ness Avenue  
Bus Rapid Transit Environmental Impact  
Statement/Environmental Impact Report Transportation  
Modeling

1650 Mission St.  
Suite 400  
San Francisco,  
CA 94103-2479

Reception:  
**415.558.6378**

Fax:  
**415.558.6409**

Planning  
Information:  
**415.558.6377**

This memo is intended to explain assumptions of the Planning Department's land use allocation, and their relationship to the Association of Bay Area Governments ("ABAG") projections, for the Van Ness Avenue Bus Rapid Transit (BRT) Project Transportation Analysis to support the Environmental Impact Statement/Environmental Impact Report (EIS/EIR) lead by the San Francisco County Transportation Authority ("SFCTA"). The Planning Department updates and maintains a land use forecast to aid in policy deliberation and decision making on the city's land use future, as well as form the basis for testing transportation impacts of new projects or plans. The fundamental basis for the land use forecasts has for more than a decade been the citywide growth projections from ABAG. ABAG issues biennial projections for population, jobs and households, and since 2003 these projections were issued reflecting a strategic effort to focus regional growth where existing infrastructure can be leveraged. In parallel with this regional effort, San Francisco has, through a number of planning efforts, sought to accommodate its growth by focusing on central locations and ensuring commensurate mitigations through the CEQA process. More details on the allocation itself are available in a memo on the Land Use Allocation 2007.<sup>1</sup>

## **General ABAG Compliance**

The Land Use Allocation ("LUA") is made to be consistent with ABAG's 2007-series projections. State of California Government Code 65089 states that data bases (i.e., land use inputs) for models such as SF-CHAMP used to determine quantitative impacts of development on the circulation system "...shall be consistent with the data bases used by the regional planning agency [i.e., MTC]". For this reason, land use projections used in the SF-CHAMP model for EIRs led by the San Francisco Planning Department as well as the Van Ness Avenue BRT Project EIS/EIR are within 1% of regional ABAG projections for population, employed residents, households, and employment. The allocation and transportation model together are accordingly consistent with the Regional Transportation Plan pursuant to CEQA Guidelines Section 15130(b)(1)(B). With this consistency, different projects can be evaluated against a consistent baseline to

---

Figure 1 ABAG Household Projections from different years. Source: ABAG

make various analyses more comparable relative to what would have been the case in the absence of such consistency.

ABAG projections have themselves undergone a change in philosophy during the past decade (see Figure 1). Unlike earlier ABAG projections issued prior to 2002, *Projections 2007* (“P2007”) adjusted assumptions about the regional growth distribution, focusing more growth in core areas of the region, including San Francisco. This is consistent with trends of

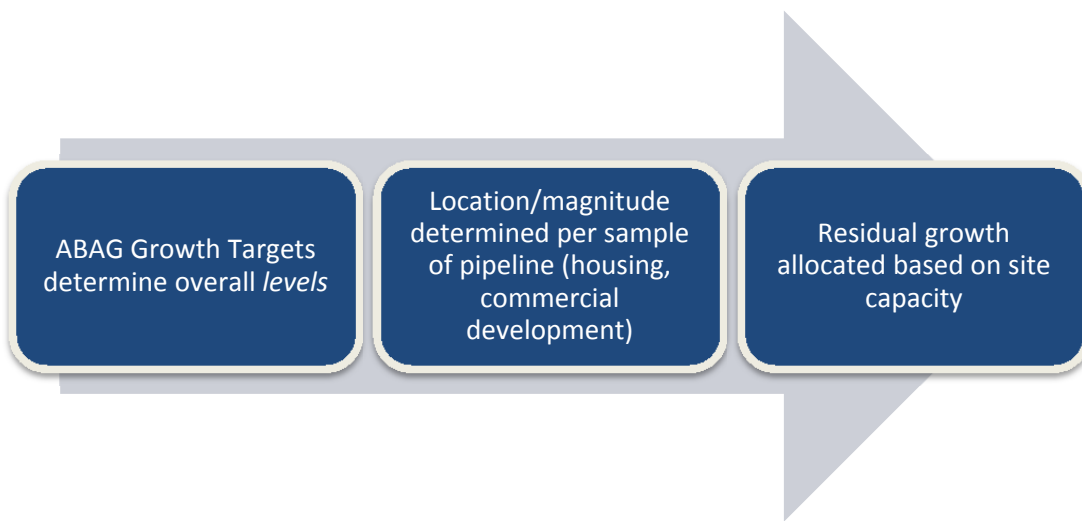

the past decade showing higher amounts of growth in San Francisco relative to historical levels for the city. The fact that ABAG’s projections assume a change in “business as usual” with respect to the location of growth appears more empirically plausible given the accelerated growth in San Francisco during the past decade.

Ultimately, regulatory consistency means that the projections from ABAG are taken as externally given constraints, “control totals” or “growth targets” on the allocation, representing the total amount of growth the city will experience by a given time frame given regional economic assumptions. The main components going into the Planning Department’s allocation of ABAG’s citywide growth targets to Travel Analysis Zones (TAZs) are 1) growth allocated according to the development pipeline, and 2) growth allocated according to estimated capacity on currently underutilized sites, favoring zones with established activity centers (household or jobs).

The Development Pipeline consists of known<sup>2</sup> development projects that would add residential units or commercial space, applications for which have been formally submitted to the Planning Department or the Department of Building Inspection (DBI). As of early 2008, the time of preparation of this projection, pipeline activity levels were at a long time high, adding up to some 54,000 units. In addition to this number comes a number of projects the Department were analyzing specifically at the time, including the Transit Center District Plan, consisting of a changed zoning program for around 18 development sites in the Transbay area, but also plans such as Mission Bay which was well known and with good expectations as to its realization.

<sup>2</sup> The Planning Department maintains a database of projects (the “development pipeline”) as they move through the entitlement stages, obtain building permits and proceed with construction.

Adding all these components presents the challenge of remaining within the macroeconomic assumptions for overall growth for the City for the projection horizon as represented by ABAG's control totals. If everything is included, the allocation is not compliant with California Government Code 65089 (see discussion at start of section). One approach would be to assume the area plans developed in full, but was rejected because the total growth would have either significantly exceeded the ABAG control totals or would have “crowded out” the development pipeline of known projects in order to meet those control totals, neither of which was feasible or desirable from an analytical standpoint since the pipeline represented actually revealed developer interest, and as this interest comprised such a large share of the control total, it was taken to embody more immediate location information.

In order to address this issue of magnitude, a random sampling of pipeline projects was applied, and in some cases a reduction of amount developed within the projection horizon, was applied. The logic of inclusion of the magnitude of pipeline projects is enumerated further below:

- *First*, as the number of units in the pipeline, widely conceived, turned out to be higher than the entire projection for the 2005-2030 period,<sup>3</sup> an overall reduction in development was needed. If everything had been assumed built by 2030, the allocation would have failed to be regionally compliant.<sup>4</sup> The development pipeline normally exhibits attrition as projects are abandoned, delayed or fundamentally changed before completion. Based on past experience, Planning Department staff, using professional judgment, felt that some pipeline projects should not be represented with their fully proposed buildout. A random sampling was employed in part to represent this attrition.

---

<sup>3</sup> The standard LUA as provided by the Planning Department to the Transportation Authority only covered the period to 2030. For the BRT EIR/EIS, the horizon year was 2035. The last increment was handled by Transportation Authority staff by proportional extrapolation in order to match the 2035 P2007 ABAG control totals.

<sup>4</sup> It is worth noting that ABAG's 2007 Projection represented a relatively high amount of growth for the city to begin with, so this limitation did not represent an unrealistic constraint.

- *Second*, for a number of the largest projects it was assumed that they would not be fully built out by 2030, in effect scaling them for the purpose of the citywide allocation. These include Candlestick/Bayview Waterfront, Treasure Island, and Park Merced. While this serves as a useful way to ensure citywide consistency with ABAG control totals, it is not an unreasonable assumption to make (and consistent with past experience) given the magnitude and complexity of realizing these 25,000 units.
- *Third*, not everything that is going to be built during a given 25-year period is known 25 years in advance. Just as some projects are abandoned, new ones are expected to appear on an ongoing basis over the projection horizon. This segment of new projects was represented by allocating a residual growth based on existing underutilized site capacity. Since the residential pipeline was reduced by sampling due to its large size, this applies mostly to non-residential development.

Generally, area plans such as Market Octavia and the Eastern Neighborhood suite (Mission, Showplace Square/Potrero Hill, Central Waterfront and East Soma) were treated as development *capacity* that could *enable* growth, rather than growth that would deterministically happen. This is consistent with what the plans are—a change to zoning controls bundled with fees on development, ensuring impacts are offset as growth proceeds, enabling private developers to over time develop – or not as the case may be—property according to the updated zoning designations. But zoned capacity is no guarantee that development will happen; and as it is, more than 73,000 units could be developed under current zoning throughout the city.<sup>5</sup> Thus zoning plans, each representing for some areas several thousand parcels with scattered ownership, differ in nature from more defined projects such as Mission Bay and the Transit Center District Plan mentioned earlier, as each of these are characterized by a much more limited number of parcels and land owners, and/or the developer and funding sources may already be identified. A key constraint on residential development assumptions was then ABAG’s control totals, even as they had been significantly expanded relative to their previous projections series. This constraint was less salient on the non-residential side, because the pipeline did not exceed the ABAG control total for jobs. As such, jobs were in large part allocated first per the development pipeline proportional to development potential.

A sample of key projects included in the vicinity of Van Ness for the land use projections are the CPMC Cathedral Hill hospital project; tower projects at Market and Van Ness and Market and Mission; the new building for the Public Utilities Commission on Golden Gate Ave; a residential tower at 10<sup>th</sup> and Market; the Trinity Plaza development; and a residential tower on 9<sup>th</sup> and Market. Figure 3 shows allocated growth in the vicinity and beyond for households and jobs, respectively.

### Introduction and General Notes

This summary specifies the main steps used to allocate ABAG's *Projections 2007* (P2007) of employment growth from 2000 to 2030 for the City & County of San Francisco to the 981 Traffic Analysis Zones (TAZ's) of the San Francisco County Transportation Authority (SFCTA or TA).

The Planning Department updates and maintains a land use forecast to aid in policy deliberation and decision making on the city's land use future, as well as form the basis for testing transportation impacts of new projects or plans. The basis for the land use forecasts has for a number of years been the citywide projections from the Association of Bay Area Governments (ABAG). ABAG issues biennial projections for population, jobs and households, and since 2003 these projections were performed reflecting a strategic effort to focus regional growth where existing infrastructure can be leveraged.

Larger macro-economic conditions are taken as given as reflected in ABAG P2007. The purpose of Land Use Allocation 2007 is to distribute the citywide growth targets (control totals) from ABAG P2007 to 981 distinct TAZ's. The Planning Department categorizes land uses not by industrial activity, but by a land use classification system crafted to reflect distinct land use characteristics of a given economic activity.<sup>1</sup> These land use categories are in turn understood by SF-CHAMP, the activity-based transportation model maintained by the San Francisco County Transportation Authority.

---

<sup>1</sup> The Planning Department employs a classification of economic activities according to their land use characteristics for the purposes of land use and transportation analysis. The scheme is referenced in the San Francisco Administrative Code, Chapter 38, Transit Impact Development Fee, §§38.1(H), (J), (K), (M), (N), (U), (EE). The categories are spelled out in Table 5 ABAG Projections Series 2007 Converted to Landuse Sectors.

The base year for this exercise is year 2005 as that represents our best available disaggregate count of housing units and households, as census blocks can easily be aggregated to TAZs. As for TAZ-level employment counts, these were taken from Dun & Bradstreet 2004<sup>2</sup>, the dataset deemed most accurate in terms of number and location of businesses. The employment counts have at the establishment level been amplified slightly to match ABAG's sector-wide control totals for the year 2005.

The allocation is implemented in Microsoft Access and draws on a number of tables external to the allocation database itself; chiefly the pipeline and the buildout databases, but also a table of developments since 2005 as well as a table containing information on programmed development. As the MS Access .mdb file serves as the container for the personal geodatabase for use in Arcgis, with changes made in these externally linked tables, new model outputs can be automatically generated and mapped.

**There are 8 overall steps to the allocation:**

1. Convert control totals from P2007 to the Planning Department's land use sectors to work as land use specific growth targets for each five-year increment. (Six land use sectors times five increment periods equals 30 data points to match with the allocation.)
2. Summarize growth in the pipeline and other planning programs and summarize by TAZ by sector, for years 2010, 2015, etc.
3. Assume vacant space is partially filled over the allocation period and grow employment relative to 2005 numbers.
4. Determine residual growth to be allocated in addition to pipeline and filled vacant space.
5. Determine buildout capacity in terms of PDR and MIPS and OTHER square footage for each parcel in the city as a function of current and/or proposed zoning, and summarize by TAZ. Assign to each TAZ the portion of citywide PDR, MIPS and OTHER square footage it comprises.
6. Summarize existing (2005) commercial square footage/housing units by sector by TAZ and determine each TAZ's share of citywide totals.
7. Based on steps 5 and 6, construct for each TAZ for each sector a weighed measure for each TAZ determining the attractiveness of a parcel for development. A TAZ with plenty of capacity, but little existing activity, will not be as attractive as a TAZ with some capacity and plenty of existing activity. Each weight is then converted to a proportion of citywide weights and multiplied the residual from step 4 to get TAZ-specific growth for each sector, and housing units. These are summed with the contribution from the pipeline and vacancy fill, and total growth is known. Result: households and jobs for each sector for each TAZ.

---

<sup>2</sup> Employment numbers for Treasure Island come from Dun & Bradstreet 2005.

8. After each allocation period, subtract allocated space from capacity table. These updated capacities will form the basis of the weights in the subsequent period.

The steps are expanded below:

## 1. Convert control totals from P2007 to the Planning Department's land use sectors.

- a. Purpose
  - i. ABAG's numbers represent macro-economic trends for the city and thus serve as the benchmark against which growth is measured.
  - ii. ABAG's numbers must be converted to the Planning Department's land use sectors for use in this allocation.
- b. Determine relation between NAICS and land use sectors, i.e. assess how one ABAG NAICS category aggregation is distributed along the Planning Department's land use categories. (Jobs in ABAG's general category *Health, Educational And Recreational Service Jobs*, itself an aggregation of NAICS classes, for instance, are in several different land use categories, including *Cultural, Institutional, Educational; Medical; and Retail*. Each business was cross-classified in both systems and the result cross-tabulated to reveal the aggregate result. This was done for the 2004 Dun & Bradstreet dataset by converting NAICS classification to SIC, then assigning land use sector based on the SIC code and location.
- c. Assuming that the relation between these classification systems remain constant over time (not the actual numbers), we converted ABAG's 2005, 2010, 2015, 2020, 2025 and 2030 control totals to the Planning Department's land use sectors. A cross-tabulation was performed, summarizing employees by landuse sector on one axis and ABAG's categories on another. Employees were converted to percentages (i.e. again ABAG's general category *Health, Educational And Recreational Service Jobs* would be categorized in 32% CIE, 21% MEDICAL, 6% MIPS, and so on.) This conversion scheme was used for all ABAG control total years, getting growth by land use sectors for each increment.
- d. Accordingly, growth could be calculated for each increment, i.e. retail growth 2005-2010, 2010-2015, etc.

## 2. Summarize growth in the pipeline and other planning programs and summarize by TAZ.

- a. Purpose
  - i. The development pipeline is an important indicator and component of growth in the near to intermediate term. It serves as observed information representing interest in small and large development.
- b. The pipeline database is updated quarterly with consolidated information from Planning and Building Departments' databases and represents projects

not yet completed, ranging from permit filed to under construction. Projects vary in size and complexity, and thus likelihood of being built upon issuance of a building permit. For the purpose of the allocation, we only included projects with approved building permits or planning entitlements, and projects under construction as these are the most likely to actually be built.

- c. Pipeline projects are recorded with net square footage information by land use sector. Thus, projects with an office component will show a net positive growth in office square footage IF proposed office is larger than what is demolished, should the site not be vacant. Similarly with housing units. If a pipeline project is a conversion from one commercial category to another or demolishes existing commercial space, net negative commercial space is recorded.
- d. Pipeline net square footage is converted to jobs using job densities (Attachment 1) calculated using Dun & Bradstreet business data to which a land use category has been assigned. The dataset has employment and square footage by establishment, so average densities by sector can be calculated. Net negative square footage from the pipeline was treated the same way as net positive space, leading to occasionally sizeable job losses attributable to a demolition.
- e. Add proposed programmed development to the pipeline.
  - i. Larger projects such as Candlestick, Bayview-Hunters Point, India Basin, Treasure Island and Mission Bay are treated as full development programs with a high likelihood of being realized over the span of the forecast.
  - ii. Thus, where such a program is present, we use that as the “best guess” and close off the TAZ in question for further development allocation.
  - iii. Programmed development, measured in square feet, was converted to jobs using the densities described in 2(c).

### **3. Fill up vacant space by increasing existing employment slightly.**

- a. Purpose
  - i. According to ABAG, San Francisco lost 90,000 jobs between 2000 and 2005 as the dot-com boom turned to bust. For this reason, the Planning Department assumed that a portion of the control totals must be met not by new construction, but by re-occupation of existing space, i.e. a lowering of the vacancy rate across sectors. This ensured a more realistic geographic distribution of growth than just relying on jobs to go where construction sites are available, a method that would otherwise show little growth in the downtown area.

- b. Vacancy rates for different sectors for the different increments were estimated with an aim to roughly follow the trends in economic activity as represented by P2007. The highest vacancy rates were thus in 2005, dropping for all sectors by 2010, with slight increases later in the allocation period. The aim was not to pinpoint the actual future vacancy rate so much as to estimate relative movement trends allowing for re-occupation of vacated space in the short-to-medium term.
- c. The jobs coming from this method were based on the 2005 base year count by sector held constant. To spread out the contribution from this method (which was necessary to avoid breaching control totals), a portion was added for each increment period relative to the number of jobs present at the base year. This method does not consider vacancy of new space being built.<sup>3</sup>

**4. Determine residual growth to be allocated in addition to pipeline and filled vacant space.**

- a. Purpose
  - i. The pipeline and the filling of vacant space make up a sizeable portion of the control totals. However, there remains a residual that must be allocated by other means.
- b. With the sector-specific pipeline and vacancy contributions to jobs treated as given, the difference between the sector-specific control total and the growth from pipeline and vacancy fill sources is the residual yet to allocate by other means. Residual growth is counted in square feet<sup>4</sup> and housing units. The process for allocating this residual is described in what follows.

**5. Determine buildout capacity in terms of NET UNITS, NET PDR, MIPS and OTHER COMMERCIAL square footage for each parcel in the city**

- a. Purpose
  - i. Buildout capacity is one of two key factors used to determine the location of future residual growth.
- b. Each parcel in the city has two key characteristics: a zoning district and a height limit. This information can be used to obtain a reasonably accurate estimate of buildout potential for each parcel. For example, some districts limit the number of housing units per lot; others have a limit as a function of lot size, whereas lot cover and setbacks are stipulated for others. Knowing this information and what is currently on the ground, an estimate of net potential can be calculated.

---

<sup>3</sup> This was dealt with separately.

<sup>4</sup> As square feet are the unit of analysis for the buildout and pipeline tables, we account using this metric for the capacity-driven portion of the allocation. Since we assume some vacancy for future years, control totals for the residual square footage are adjusted upwards to reflect this anticipated vacancy.

- i. On-the-ground information comes from a LIDAR<sup>5</sup> dataset current as of June, 2007. While accurate in terms of volume, the dataset doesn't readily provide square footage, so this must be inferred based on building height and an assumed height per floor. This is assumed to vary depending on the type of district; downtown commercial districts, for instance, are assumed to have an average ceiling height that is larger than that in residential districts.
- ii. Existing residential unit counts come from the assessor, the Census Bureau, and the Planning Department's Housing Inventories.
- iii. Some districts are undergoing a rezoning effort, including the Eastern Neighborhoods, Central Waterfront, and Market & Octavia. For these neighborhoods, the buildout potential was calculated for the proposed zoning rather than the existing zoning. For the rest of the city, existing zoning was assumed in calculating net capacity.
- iv. The net commercial capacity is further subdivided into PDR, MIPS and other commercial capacity. Each zoning district was flagged to determine whether PDR and MIPS was allowed, and in those districts where it was, a certain proportion of net commercial space was assigned as PDR and MIPS space. The remainder, and for all other parcels, the net commercial was assumed to be OTHER non-descript commercial/institutional space.
- v. Finally, the net capacity, for PDR, MIPS and other commercial capacity square footage, was summed by TAZ, and each TAZ was assigned the proportion each TAZ comprised of the total non-PDR and PDR square footage, respectively.

**6. Summarize existing (2005) commercial square footage/housing units by sector by TAZ and determine each TAZ's share of citywide totals.**

- a. Purpose
  - i. The second factor determining the geography of future growth is existing conditions. Existing conditions have been shown to be strong predictors of future growth.
- b. Existing square footage by sector at the TAZ-level is used as an indicator of local attractiveness of a certain TAZ for a certain activity. This measure will be made into a composite weight measure balancing capacity with attractiveness. This is essentially a gross-level agglomeration economics measure suggesting that like attracts like.

---

<sup>5</sup> "Light Detection and Ranging", a remote sensing system used to collect three-dimensional topographic data, was used to estimate existing building square footage.

- c. Produce a composite weight measure<sup>6</sup> based on step 5(b)(v) and step 6(b). The measure is constructed as follows:

$$\text{Constant1} * \text{MIPS\_EXIST\_2005}_{\text{TAZi}} + \text{Constant2} * \text{MIPS\_CAP\_20xx}_{\text{TAZi}}$$

Where

Constant1 = a manual weight regulating importance of measures

Constant2 = a manual weight regulating importance of measures

MIPS\_EXIST\_2005TAZi = Proportion of total 2005 MIPS sqft in TAZi

MIPS\_CAP\_20xxTAZi = Proportion of total 20xx MIPS capacity sqft in TAZi

- d. The composite measure is then itself converted to a percentage of the total of citywide weight measures, allowing for multiplication with the residual.

**7. Multiply the proportions from Step 6(d) with the growth residual from Step 4, and sum with the contributions from the pipeline and vacancy fill.**

- a. The total residual sector-specific square footage, or remaining growth to be allocated after the pipeline and vacancy fill, is distributed according to the proportions from Step 6(d): For each sector, multiply residual growth (whether as sector or households<sup>7</sup>), counted in square footage, by percentages from step 6(d).
- b. Sum the residual result with the pipeline growth. Result: Total allocation, PDR jobs, non-PDR jobs

**8. End of Period Accounting: Subtract allocated space from capacity table.**

- a. After each allocation period, what was allocated must be subtracted from the capacity table so this table and the derived coefficients calculated for at the onset of the following allocation period, is current. This is done in sequence following each sector allocation. The allocation sequence, and in turn capacity subtraction, is MIPS, RETAIL, CIE, MED, VISITOR and PDR.<sup>8</sup>
- b. As there is programmed development assumed to take place, this is given precedence in cases where programmed growth for a given sector exceeds that allotted by the control total. In such cases, to offset excess in one period,

<sup>6</sup> Incidentally, using a weight based on existing conditions and future potential is similar to the Census Tract Allocation (SAM), the final leg of ABAG's forecast framework which distributes growth to tracts within a subarea.

<sup>7</sup> Housing units is the unit of analysis in the pipeline and capacity table; the control total is measured in households and converted to housing units by assuming a 5 % vacancy. (There are thus slightly more housing units to be produced than the number of households listed by ABAG.)

<sup>8</sup> The order in a sense doesn't matter as much as it appears since capacity is counted separately for MIPS, PDR, and OTHER COMMERCIAL.

discretionary growth<sup>9</sup> was offset in the following allocation period for the sector in question.

- c. This process of determining pipeline and vacancy contributions to growth, capacity by sector, calculating new coefficients to allocate the residual, monitoring excess allocation and next period growth adjustment, is repeated for each five-year increment.

## Data Pre-Processing

As different data sources differ in how proposed and existing uses are counted and categorized, it was necessary to map input source classifications to the land use system used by the Planning Department. The Bayshore figures from Lennar included a Research and Development classification which, while substantively meaningful, has yet to be defined in the land use classification system currently used. In treating Bayshore as a special case, it was decided to treat R&D as a hybrid of MIPS and PDR land uses for transportation and job density purposes; any space in the Bayshore region designated on the input side as R&D would be mapped to 75% MIPS space, 25% PDR space.<sup>10</sup>

For Mission Bay, our source data was less unequivocal about the nature of the space, and it was accordingly mapped to either MIPS or MEDICAL, not the hybrid as described for Bayshore. While this may seem somewhat inconsistent, there were strong reasons to treat Bayshore as a special case and not use the same strategy for Mission Bay. Apart from the less explicit classification on the input side (often a project would be described as office/R&D), to map the large amount of square footage in Mission Bay out to PDR would lead to both misleading inconsistencies with the control totals on the demand side as well as problems of PDR capacity on the supply side. It should in this context be noted that while much space in Mission Bay was mapped to MIPS/office, it may strictly speaking be a mix of other, but in substance similar uses, and the allocation effort should not be construed as an endorsement nor entitlement of construction of office space as regulated and limited by Planning Code §§320-322.

## ABAG Compliance

The intent was for the allocation to be ABAG-compliant. Unlike earlier ABAG projections, which were much more conservative, P2007 is much more expansive with respect to the growth it projects. Because of this higher growth, and to better match numbers used by other agencies in the City and beyond, it was decided to aim for project runs to be ABAG-compliant, essentially assuming a zero-sum growth within city boundaries. If one project happens, it will, in this allocation, result in less growth elsewhere. The notable exception to

---

<sup>9</sup> Discretionary growth refers to the residual growth after the pipeline and vacancy has been filled.

<sup>10</sup> For example, 100,000 square feet of R&D would be mapped to 75,000 sq. ft. of office space and 25,000 sq. ft. of PDR space, and each converted to jobs applying respective density rates.

this is where programmed development exceeds the control total for a given sector. As noted in step 8(b), such cases of programmed growth in excess of the control total would be offset in the subsequent period in the portion of discretionary growth. If the next period has a high amount of programmed growth as well (and thus little discretionary growth from which to offset), the allocation will exceed the ABAG control total. With macro-economic conditions constant, development beyond the control totals could result in higher vacancies and/or lower prices, but these have not been modeled as a part of this effort, the primary purpose of which was to show a “what-if”-scenario of a set of specific proposed development programs.

# Attachment 1

## Constants Used

**Table 1 Estimated Vacancy Rates <sup>/1/</sup>**

Vacancy	MIPS	RETAIL	VISIT <sup>/3/</sup>	MED <sup>/3/</sup>	CIE <sup>/3/</sup>	PDR
2005	14.5%	8.0%	8.0%	8.0%	8.0%	7.5%
2010	12.0%	5.0%	5.0%	5.0%	5.0%	6.0%
2015	10.5%	4.5%	4.5%	4.5%	4.5%	6.0%
2020	11.0%	5.0%	5.0%	5.0%	5.0%	6.0%
2025	10.0%	6.0%	6.0%	6.0%	6.0%	6.0%
2030	9.0%	6.5%	6.5%	6.5%	6.5%	6.0%
Default Average Rate <sup>/2/</sup>	10.0%	6.0%	6.0%	6.0%	6.0%	5.0%

/1/ Rates were used to calculate extra jobs moving into vacated space. The MIPS vacancy range was deliberately compressed in order to keep vacancy fill well within control totals.

/2/ the Default Average Rate was used when converting proposed square footage into actual jobs (proposed programmed development), and when converting an ABAG job control total into square feet to build. Thus accounting for vacant space, to reach the number of jobs in the control totals, slightly more space will need to be built.

/3/ While the interpretation of vacancy for MIPS, RETAIL and PDR space is fairly straightforward, it is somewhat less so for the CIE, MED and VISITOR sectors. For the larger institutional uses in CIE and MED categories because they often appear in larger discrete portions which are either occupied or not (like schools, museums or hospitals); for VISITOR uses because the metric is entirely different (room occupancy) and seasonal. Vacancy rates for those sectors may thus be more theoretical than practical.

## Fwd: SFCTA Model Consistency 2009

---

Elizabeth Sall <elizabeth@sfcta.org>  
To: Michael Schwartz <Michael.schwartz@sfcta.org>

Fri, Jun 7, 2013 at 4:23 PM

----- Forwarded message -----

From: **David Ory** <DOry@mtc.ca.gov>  
Date: Fri, Jun 7, 2013 at 4:22 PM  
Subject: SFCTA Model Consistency 2009  
To: Elizabeth Sall <elizabeth@sfcta.org>

Dear Elizabeth,

This email confirms that I verbally approved SFCTA's Modeling Consistency requirement for the 2009 CMP.

Kindest Regards,

Dr. David T. Ory

Principal, Planning

## Cross Transit Delay and Travel Time Reduction Proposals

# Memorandum

**Date:** 07/02/2013  
**To:** Tilly Chang, Deputy Director for Planning  
**From:** Michael Schwartz, Senior Transportation Planner  
**Subject:** Van Ness BRT Cross Transit Delay Analysis

This memorandum summarizes the potential delay to transit vehicles crossing Van Ness Avenue that could result from implementation of the Van Ness Bus Rapid Transit (BRT) project. The analysis was done in response to comments received by the San Francisco County Transportation Authority (Authority) as part of its review of the Draft Environmental Impact Statement/Environmental Impact Report (EIS/EIR).

## BACKGROUND

The analysis uses transit delay methodology developed by Adavant Consulting, Wilbur Smith Associates (now CDM Associates), and CHS consulting in a memorandum dated October 22, 2008. This methodology was used to determine transit delay impacts for the Bicycle Plan EIR.

## METHODOLOGY

The analysis quantifies the delay that could potentially be experienced by transit vehicles crossing the Van Ness corridor from Mission Street to Lombard Street. The total transit vehicle delay is assumed to comprise of the following cumulative elements:

- **Traffic Congestion Delay** - The traffic congestion delay represents the additional time experienced by a transit vehicle as it travels between stops across one or more intersections in the corridor due to congestion caused by other vehicular traffic traveling parallel or perpendicular to the transit flow.
- **Passenger Boarding Delay** - The additional dwell time incurred by transit vehicles at stops waiting for passengers to board and pay the fare.<sup>1</sup>
- **Transit Reentry Delay** - The transit reentry delay represents the wait for a sufficient gap in traffic flow to allow a bus to pull back from its stop into the travel lane.

Since intersection congestion in the study area currently is, and would continue to be, most severe during the weekday PM peak hour, this time period was evaluated for the effects to SFMTA transit operations.

As the significance criteria consider only the incremental increase in transit travel time as a result of the project (i.e., greater than 50% of the route's headway during the PM peak), the transit travel time

---

<sup>1</sup> Delay due to passenger alighting is captured within the passenger boarding delay because passengers can exit and enter via all doors on a transit vehicle.

evaluation only considers the following scenarios:

- 2007 Existing Conditions
- 2035 Baseline (No Build) Alternative (considered to be the baseline for the analysis);
- 2035 Baseline plus Project Alternative.

Since traffic diversions and delays are higher in 2035 than 2015, this represents the worst case scenario. Similarly, since Design Option B (LPA) is expected to have the highest rate and number of diversions, this also represents a worst case scenario. Using the following criteria, each measure of transit delay was calculated for each of the 50 crossing routes with PM service at the station on or closest to Van Ness Avenue.

**Traffic congestion delay:** Increased traffic congestion along transit routes slows down transit vehicles and results in increased transit travel times. Congestion delay was quantified from the results of the intersection operations analysis performed in SYNCHRO for the study area. For every transit line that crosses Van Ness Avenue, the transit delay was estimated as the average delay per vehicle at the individual intersection movements through which the transit line would operate. The additional traffic congestion delay was calculated as the difference between the delay in the 2035 No Build scenario and 2007 Base Year, between the 2035 Project scenario and 2007 Base Year, and between the 2035 Project Scenario and 2035 No Build scenario. For transit lines that operate within a transit-only lane (i.e., those operating on Market and Geary streets), the transit delay can be estimated as half the average red time at the controlling traffic signal (as transit vehicles would not be subject to the congestion experienced by regular traffic at these locations). Because the signal timing is not projected to change between scenarios, transit lines in transit only lanes (e.g. the 38 and 38L) do not experience additional traffic congestion delay.

**Passenger boarding delay:**<sup>2</sup> Although increases in transit ridership are generally viewed as a project benefit, the amount of time required for passenger boarding and alighting (i.e., the dwell time) is directly correlated to the number of passengers boarding the transit vehicle. As transit ridership increases, transit vehicles would have to spend more time at stops, which may increase overall transit travel times, which could impact service. Passenger boarding delay was estimated by examining the increase in transit ridership on individual buses generated from existing conditions to the 2035 No Build Alternative and again to the 2035 Baseline plus Project Alternative to understand the ridership impacts of the project in the context of background growth. Passenger boardings were estimated by applying a growth factor between existing conditions (2007), 2035 No Build, and 2035 Baseline Plus Project derived from SF-CHAMP, the Authority's activity-based travel demand model. The growth factor was applied to Automatic Passenger Counter (APC) ridership data from 2007 to estimate new passenger boardings in the 2035 No Build Alternative and 2035 Baseline Plus Project Alternative scenarios. Passenger boarding delay was then calculated by multiplying the change in boardings by an average boarding time, assumed to be two seconds per passenger for buses and 0.5 seconds per passenger for light rail vehicles, consistent with assumptions for VISSIM model used for the Van Ness Avenue BRT EIS/EIR (see VISSIM Data Portfolio as part of Van Ness Avenue BRT Vehicular Traffic Analysis Technical Memorandum).

**Transit re-entry delay:** Transit vehicles typically experience delays after stopping to pick-up and drop-off passengers while waiting for gaps in adjacent street traffic in order to pull out of bus stops. As traffic volumes on the adjacent street increase, re-entering the flow of traffic becomes more difficult and transit vehicles experience increased delay. For this analysis, re-entry delay was not calculated for each individual crossing route. Instead, the difference between the threshold for significant delay (assumed

---

<sup>2</sup> It is assumed that the additional travel and boarding delay as a result of the Van Ness BRT project to cross transit routes would be limited to the stop closest to Van Ness Avenue.

to be ½ of a transit route’s headway), and the sum of the transit travel and passenger boarding delays as calculated above, is reported. In other words, the maximum acceptable transit re-entry delay is calculated for each route. Based on empirical data presented in the 2000 Highway Capacity Manual, a transit re-entry delay of 14 seconds is expected where traffic volumes in the adjacent travel lane exceed 1000 vehicles/hour. It is assumed that re-entry delay would be minimal for buses or rail vehicles operating in transit-only lanes.

**Total Transit Delay:** The total transit delay for each transit line that operates within the study area was calculated as the sum of the traffic congestion and passenger boarding delays. This additional travel time is assumed to be potentially significant if greater than 50% of a transit line’s headway in the project year. The additional transit re-entry delay that would put a given line over the threshold was examined in cases where the transit travel and passenger boarding delays were close to meeting the threshold.

## RESULTS

Of the 50 routes with PM-service crossing Van Ness Avenue, none exceed the 50% average PM headway threshold in the 2035 Baseline plus Project scenario. Two transit lines are expected to have incremental delays between 25% and 50% of a headway (the 31 inbound and the 38L outbound). The re-entry delay in both cases would have to exceed a minute for the 50% headway threshold to be exceeded in the case of the 31, and is not applicable to the 38L because it operates in a transit only lane. Based on the SFMTA Transportation Engineering’s Draft Travel Time Reduction Proposals: Transit Preferential Toolkit (SFMTA, 2012; see Attachment 1), pull out delay averages 5 seconds per the benefits anticipated through bus bulbs. This is significantly less than the delay required for there to be a significant impact for the 31 (more than a minute).

The table below shows the delay for cross transit routes with expected delays above 20% of average headways during the PM peak.

**Table 1: Cross Transit Delay (Most Delayed Routes)**

Line	Cross Street	Total Additional Delay (sec)			Additional Delay as Percent of Headway			Re-Entry Time to Exceed Threshold (sec)		
		2007 to 2035 No Build	2035 No Build to 2035 BRT	2007 to 2035 BRT	2007 to 2035 No Build	2035 No Build to 2035 BRT	2007 to 2035 BRT	2007 to 2035 No Build	2035 No Build to 2035 BRT	2007 to 2035 BRT
MUN31I	Eddy	48	190	238	8%	32%	40%	252	110	62
MUN38LO	Geary	25	4	29	21%	4%	25%	35	56	31
MUN1I	Clay	50	-8	42	28%	-4%	23%	40	98	48
MUN71I	Market	70	62	132	12%	10%	22%	230	238	168
MUN6I	Market	78	54	132	13%	9%	22%	222	246	168
MUN21O	Hayes	91	0	91	22%	0%	22%	119	210	119
MUN1O	Sacramento	-4	40	36	-2%	22%	20%	94	50	54

The last three columns show the reentry time that would result in a transit line exceeding the 50% headway delay threshold. Again, with average re-entry delay anticipated to be 5 seconds per stop/intersection (source: SFMTA, 2012; for the 38L, there would be no re-entry delay because the route travels in a transit only lane), none of the routes would exceed the threshold.

Appendix A lists the expected delay for all transit routes. For 23 of the 50 routes, the BRT Project is expected to reduce or produce no added delay when compared to Baseline Conditions.

## CONCLUSION

Based on the transit travel delay analysis above, the Van Ness BRT Project is not expected to incur a significant travel time delay on any transit route crossing Van Ness Avenue.

TRAVEL TIME  
REDUCTION  
PROPOSALS:  
  
TRANSIT  
PREFERENTIAL  
TOOLKIT

---

## INTRODUCTION

---

This transit preferential toolkit provides a description of common measures to reduce transit travel time, including planning-level cost estimates and estimated travel time savings. Excluded in this list are changes related to the design and operation of transit vehicles themselves, such as low-floor buses or all-door boarding. Estimated travel time savings are provided for individual measures, although some measures have greater travel time savings if applied through an entire corridor. Travel time savings may vary greatly depending on context and only detailed analysis can provide reliable estimates for particular locations. Information is provided on where these measures may generally be applied and potential implementation challenges.

## SOURCES OF DELAY

---

Each transit preferential toolkit measure can reduce transit travel time by reducing one or more of the following elements of transit delay:

- **Transit stop delay.** Delay caused by decelerating and pulling into a transit stop.
- **Dwell delay.** Delay caused by Muni customers entering and leaving the transit vehicle. Measured from opening of doors to closing of doors.
- **Merge delay.** Delay caused by transit vehicle merging back into traffic after serving a transit stop.
- **Congestion delay.** Delay caused by traffic queues, such as those due to turning traffic waiting for gaps in crossing pedestrians or general traffic congestion.
- **Traffic signal delay.** Delay caused by a traffic signal, including stopped and congestion delay.
- **STOP sign delay.** Delay caused by a STOP sign, including deceleration and congestion.
- **Parking delay.** Delay caused by delivery vehicles, parking maneuvers, driveways, and other on-street parking friction factors.

The most cost-effective measures for reducing transit travel time are generally transit stop removal or consolidation and transit signal priority. These measures remove the most common sources of stopped delay with the lowest relative costs. As transit signal priority is being implemented through a separate Agency effort, it is not addressed in this document.

## TRAVEL TIME SAVINGS

---

Transit travel time savings can directly benefit customers through reduced travel times and can indirectly benefit the SFMTA through reduced operating costs. Many of the measures also improve transit reliability by reducing or eliminating sources of intermittent delays. Of the measures outlined in this report, only transit stop removal or consolidation may potentially increase total trip times for some customers due to an increased walking distance to/from transit stops. However, in many cases the additional time required to access a transit stop may be offset by reduced travel time onboard a transit vehicle. To maximize the potential operating cost savings resulting from travel time savings, scheduling must be monitored and adjusted. In

exceptional cases, travel time savings along a transit route may be significant enough to reduce the number of vehicles and operators required to maintain the same frequency of service. Methodology and Planning Assumptions

The estimated travel time savings and costs provided in this report are intended to communicate the relative benefits and costs of each element and may require further refinement as location-specific proposals are developed. The estimated travel time savings provided in this report are generally applicable to peak period conditions in the peak direction of transit travel and are based on a combination of SFMTA’s own analysis and experience, as well as industry reports on other agency experiences. The cost estimates provided in this report are based on past SFMTA projects, but construction costs can vary widely based on specific site conditions. Methodologies to estimate the monetary value of customers’ time have been proposed but are included in this report.

### Estimated Travel Time Savings and Costs by Measure

Measure	Scenario	Estimated Travel Time Savings*	Estimated Cost*
1. Remove or Consolidate Transit Stops	Bus, near-side at all-way STOP	5 seconds	\$3,000
	Bus, far-side or uncontrolled	15 seconds	
	Bus, nearside at traffic signal	20 seconds	
	Light rail vehicle, near-side at all-way STOP	15 seconds	\$3,000 if no boarding island / \$25,000 if need to remove boarding island
	Light rail vehicle, far-side at all-way STOP or uncontrolled	30 seconds	
	Light rail vehicle, at traffic signal	30 seconds	
2. Optimize Transit Stop Locations at Intersections	Move far-side bus stop to near-side at STOP sign	15 seconds	\$3,000 (no island) / Up to \$350,000 (with island, assumes adding key stop)
	Move near-side rail flag stop to far-side at signal; or near-side bus stop to far-side at signal	20 seconds	
	Move far-side rail flag stop to near-side at STOP sign	30 seconds	
3. Install Transit Bulbs	Install transit bulb at existing transit zone	5 seconds	\$200,000
	Extend existing transit bulb	(Time saved by extending zone)	\$100,000
	Remove existing transit bulb	(Time saved by removing stop)	\$50,000

Measure	Scenario	Estimated Travel Time Savings*	Estimated Cost*
4. Install Transit Boarding Islands	Low to moderate traffic delay (bus)	5 seconds	\$200,000
	Low to moderate traffic delay (rail, assumes key stop)	5 seconds	Up to \$500,000
	High volume right turning traffic delay (rail assumes key stop)	variable	\$100,000 (bus) / \$350,000 (rail)
	Extension of existing island (rail)	(Time saved by extending zone)	Up to \$350,000 (assumes addition of key stop)
5. Optimize Transit Stop Lengths	Extend transit zone to accommodate two vehicles at a time	2 seconds	\$3,000
6. Convert Flag Stops to Transit Zones	Adding a transit zone at an existing flag stop	5 seconds	\$3,000
7. Establish Transit-Only Lanes	Suitable corridor with high transit volume frequencies	5 to 30 seconds	\$10,000 (text and signage only)/ \$35,000 (colored pavement) per block per direction
8. Establish Transit Queue Jump/Bypass Lanes	Removal of parking where justified. Low right turning traffic friction delay.	5 seconds to 30 seconds	\$5,000; up to \$200,000 if signalized
9. Establish Dedicated Turn Lanes	High pedestrian activity or traffic volumes causing turn delay	5 seconds	\$3,000 for no signal modification; \$10,000 if already 2070 / \$30,000 if controller upgrade / \$200,000 if full upgrade
10. Widen Travel Lanes through Lane Reductions	Corridors with substandard lane widths	5 seconds to 30 seconds	\$10,000 per block per direction

Measure	Scenario	Estimated Travel Time Savings*	Estimated Cost*
11. Implement Turn Restrictions	High pedestrian activity or traffic volumes causing turn delay	5 seconds	\$3,000 per intersection for striping and signage; higher if other infrastructure added
12. Widen Travel Lanes through Parking Restrictions	Corridors with substandard lane widths	5 seconds to 30 seconds	\$10,000 per block per direction
13. Install Traffic Signals at Uncontrolled and Two-way STOP-Controlled Intersections		None	\$400,000
14. Install Traffic Signals at All-way STOP-Controlled Intersections	Bus at low volume intersection	10 seconds	\$400,000
	Bus at moderate volume major and low volume minor street, actuated; Rail at low volume intersection	20 seconds	
	Bus at congested major street; Rail at moderate volume or congested major street	30 seconds	
15. Replace All-Way STOP-Controlled Intersections with Traffic Calming Measures	Bus at low volume intersection	10 seconds	Varies by device
	Bus at moderate volume major and low volume minor street, actuated; Rail at low volume intersection	20 seconds	
	Bus at congested major street; Rail at moderate volume or congested major street	30 seconds	
16. Install Pedestrian Refuge Islands	Transit Stop	5 seconds	\$25,000
	Non-transit stop	2 seconds	\$25,000
17. Install Pedestrian Bulbs	Install pedestrian bulb	2 seconds	\$100,000
18. Widen Sidewalk		None	Varies

\*Generalized estimates; time savings and cost may vary by location.

## TRAVEL TIME REDUCTION MEASURES

### 1. REMOVE OR CONSOLIDATE TRANSIT STOPS

- What it is:** Removing closely spaced transit stops can decrease transit travel times by reducing the frequency that transit vehicles must stop to pick-up and drop-off customers. Consolidating transit stops involves removing two adjacent transit stops and establishing a new transit stop at an intermediate location.
- How it works:** The TEP's Planning Phase analysis found that about 70% of the SFMTA's transit stops were spaced closer than 800' along bus routes and 1000' along rail lines. Reducing the number of transit stops in accordance with transit stop-spacing guidelines developed as part of the TEP Policy Framework can reduce delays while maintaining a high level of customer access to transit stops. Where transit stops with established transit zones are removed, the resulting space can be used for parking, loading zones, bike corrals, parklets, parking restrictions at intersection approaches to improve pedestrian visibility and sight distance or other uses. Consolidating two transit stops into a new intermediate transit stop may require removal of parking at the new transit stop, but the net impact on parking can be minimized by restoring parking at removed transit stops. Establishing new transit stops where color curb zones exist may require converting nearby general parking into replacement color curb zones to continue to accommodate loading needs or disabled parking.
- Application:** Removal or consolidation of transit stops should be implemented in accordance with transit stop-spacing guidelines developed as part of the TEP Policy Framework.
- Estimated Cost:** \$3,000 per transit stop; \$25,000 per transit stop with boarding island removal.
- Time Savings:** Estimated travel time savings of 5 to 30 seconds per transit stop removed, depending on traffic controls and vehicular volumes and accounting for the likelihood that a given bus would need to stop and other factors. Past SFMTA experience indicates that a typical bus takes about 20 seconds to decelerate and come to a stop, open and close doors (not including dwell time between opening and closing doors), and merge back into traffic and resume normal speed. Dwell time savings are not included since they are expected to be offset by added dwell time at adjacent transit stops. Travel time savings are estimated to be greater for light rail vehicles due to their slower acceleration/deceleration and door cycling times. Travel time savings may be reduced where lightly used transit stops are removed or where transit stops located at the near-side of intersections controlled by STOP signs are removed, since transit vehicles would still be required to stop at these intersections. During off-peak periods travel time savings may be less at transit stops with low customer activity since not every stop is served by every transit vehicle.

<b>Scenario</b>		<b>Estimated Travel Time Savings</b>
Bus stop removal	Near-side at STOP sign	Up to 5 seconds
	Far-side at STOP sign or uncontrolled	Up to 15 seconds

	At traffic signal	Up to 20 seconds
Light rail vehicle stop removal	Near-side at STOP sign	Up to 15 seconds
	Far-side at STOP sign or uncontrolled	Up to 30 seconds
	At traffic signal	Up to 30 seconds

**Challenges:** In certain areas, hills, transfer points, block lengths, and sensitive land uses may make transit stop removal or consolidation impractical. Transit stop removal or consolidation should also consider the location of intersection controls that can make certain crossing points safer for pedestrians. Where transit stop removal or consolidation is feasible, travel time savings at some stops may not be as significant if transit vehicles rarely stop due to low customer activity.

---

## 2. OPTIMIZE TRANSIT STOP LOCATIONS AT INTERSECTIONS

---

**What it is:** Placement of a transit stop either near or far-side at an intersection to reduce STOP sign or traffic signal delay.

**How it works:** Optimizing transit stop locations at intersections can decrease transit travel times by reducing the number of times transit vehicles stop at intersections controlled by STOP signs or by reducing the likelihood of transit vehicles arriving on a red signal indication at intersections controlled by traffic signals.

**Application:** At STOP-controlled intersections, it is generally recommended that transit stops be located on the near-side of the intersection to enable transit vehicles to conduct customer pick-up and drop-off while stopped at the STOP sign, rather than needing to stop a second time to conduct customer pick-up and drop-off on the far-side of the intersection. At traffic signal-controlled intersections, it is generally recommended that transit stops be located on the far-side of the intersection to allow transit vehicles to take advantage of existing and planned transit signal priority improvements that could allow traffic signals to be programmed to hold green signals for approaching transit vehicles. These recommendations are based on the assumption that the bus is traveling straight through an intersection and may not apply when a bus turns due to geometric considerations to facilitate the movement of the bus through the intersection.

**Estimated Cost:** \$3,000 per transit stop; \$350,000 per light rail transit stop including new boarding island.

**Time Savings:** Estimated travel time savings of 15 to 30 seconds per transit stop, dependent on context and traffic control devices (see table below). Minimal travel time savings are estimated where lightly used transit stops are optimized.

Scenario	Estimated Travel Time Savings
Move far-side bus stop to near-side at STOP sign	15 seconds
Move near-side rail flag stop to far-side at signal; or near-side bus stop to far-side at signal	20 seconds
Move far-side rail flag stop to near-side at STOP sign	30 seconds

Challenges: In certain areas, transfer points, route turns, on-street parking, and sensitive land uses may make ideal zone locations impractical. Midblock transit stops may not be intuitive to customers as many expect stops to be at intersections. Heavy right-turning traffic volumes may add additional challenges to near-side stops. Zones longer than one standard transit vehicle may be difficult to approve in areas with high on-street parking demand.

---

### 3. INSTALL TRANSIT BULBS

---

- What it is:** Transit bulbs are sidewalk extensions at the location of a transit stop, typically about the same width as the adjoining parking lane.
- How it works:** Transit bulbs can reduce transit travel times on bus routes by eliminating the need for buses to exit and re-enter the flow of traffic<sup>1</sup> to access curbside transit stops and by facilitating accessible boarding by allowing buses to align directly with the curb. Transit bulbs can reduce transit travel times on rail lines by providing a place for boarding customers to wait directly adjacent to a stopped light rail vehicle (LRV), thereby eliminating the time needed for customers to walk from the curb across a parking lane to the LRV.
- Application:** Transit bulbs will generally provide the greatest travel time savings at bus stops with high merge delay. However, transit bulbs have multiple benefits, including:
- a) Provision of more space for transit shelters, landscaping and related transit stop amenities.
  - b) Reduced sidewalk crowding due to loading activities.
  - c) Increased customer comfort waiting for transit service.
  - d) Improved pedestrian safety through reduced street crossing distance for pedestrians, improved pedestrian visibility and reduced speed of turning traffic.
  - e) Improved on-board customer comfort by eliminating the bus weaving in and out of a zone.

---

<sup>1</sup> Legislation to require motorists to yield to merging buses has not been adopted by the State of California

- f) Improved system safety by reducing sideswipe collisions between passing motor vehicles and stopped transit vehicles.
- g) Improved bus alignment (especially the rear of the bus) in the transit zone directly next to the curb, allowing boarding to occur directly onto the sidewalk, rather than into the street.

Dimensions will vary by site, but typical transit bulbs are 6 feet wide and use 10-foot and 20-foot transition radii. See DPW Standard Plans 87,175 for typical dimensions of transitions, available at

<http://www.sfdpw.org/ftp/uploadedfiles/sfdpw/boe/87,175.pdf>.

Typical approximate lengths for bus bulbs are shown in the table below (note that transit bulbs are not typically used for 30-foot buses as this fleet type is generally utilized on lower-volume, less frequent routes).

Stop Position (Bus Bulbs)	Type of Vehicle and Appropriate Zone Length (Ft.)			
	40' Bus	2x40' Bus	60' Bus	2x60' Bus
Midblock	35	80	55	115
Nearside	35	80	55	115
Farside	45	90	65	130
Farside (after right turn)	<i>Varies based on vehicle type (trolley or biodiesel) and lane configuration</i>			

**Estimated Cost:** \$100,000 to \$400,000 per bulb, depending on the location, with \$200,000 as a generalized estimate. Higher end estimates are based on requirements to relocate utilities, sewer catch basins, and fire hydrants. Decorative sidewalks and sub-sidewalk basements present the most significant design complications.

**Time Savings:** Estimated travel time savings of 5 seconds per bus bulb. Review of TCRP REPORT 65 "Evaluation of Bus Bulbs" indicated low travel time savings resulted from some projects. In general, transit bulbs provide the greatest travel time savings at bus stops with high merge delay. These delays can vary between a few seconds to 20 or more, depending on traffic conditions. Lower-end time savings are expected at locations with low traffic volumes and STOP sign controls. At many locations operators may not be fully pulling into transit zones consistently. At these locations, travel time may be saved through faster boarding times due to improved customer access to the transit vehicle rather than reduced merge delay.

**Challenges:** Transit bulbs require transit vehicles to block travel lanes while serving transit stops. On streets with one travel lane in a given direction there is the potential for intersections to become unintentionally blocked by motorists following the transit vehicle (far-side bulb) or for motorists to pass stopped transit vehicles on the left using an opposing traffic lane (near-side bulb). Some customer loading maneuvers

can require more than a minute to be completed. For this reason bulbs on two-lane roadways should be applied with caution. Factors to consider include the volume of affected through traffic, intersection traffic controls, and the frequency of transit service. Transit bulb design should be coordinated with the fire department to ensure access to fire hydrants is maintained and to review potential impacts to emergency response times.

---

#### 4. INSTALL TRANSIT BOARDING ISLANDS

---

What it is:	Transit boarding islands are raised islands within the street that allow transit vehicles to use a center lane within the roadway to pick-up and drop-off customers at transit stops.
How it works:	Transit boarding islands can reduce transit travel times on bus routes by eliminating the need for buses to exit and re-enter the flow of traffic to access curbside transit stops. Transit boarding islands also allow the bus to avoid the curb lane, which is generally slower as a result of parking maneuvers, right turns and illegal double parking. Transit boarding islands can reduce transit travel times on rail lines that operate on fixed guideways in the center of the street by providing a place for boarding customers to wait directly adjacent to a stopped LRV, thereby eliminating the time needed for customers to walk from the curb to the LRV.
Application:	New transit boarding islands require curb ramps. If the island is used by buses, it should be a minimum of eight-feet wide to allow for wheelchair lift deployment. Boarding islands typically used exclusively by LRVs should also be at least eight feet wide where feasible to allow for the occasional replacement of LRV service with substitute bus service. All new LRV boarding islands constructed must provide access to LRVS (e.g. high-level boarding or a mini-high platform) unless the grade of the street makes it structurally impracticable. Pedestrian railings may be included. Installation of boarding islands on streets with grades must be carefully reviewed to ensure accessibility requirements are met (typically slope cannot exceed 8.33%).
Estimated Cost:	\$50,000 to \$200,000 or more per island along bus routes, depending on drainage issues; Up to \$500,000 per island along rail lines with mini-high platform for accessible boarding.
Time Savings:	Estimated travel time savings of 5 seconds per island. Travel time savings will vary by intersection along bus routes depending on traffic conditions, particularly the level of traffic using curbside lanes versus center lanes.
Challenges:	Many streets do not have the necessary width required to accommodate transit boarding islands. Transit boarding islands can be less convenient for customers than curbside stops and in some locations sidewalks offer more space for customer amenities. Boarding islands may encourage pedestrians to cross outside crosswalks. At some intersections center lane may be congested as well, particularly from left turning traffic. Turning prohibitions can be considered but these may affect local circulation. The placement of boarding islands must consider vehicle access to driveways and vehicle turning movement; in particular far-side boarding islands may interfere with vehicles turning from cross streets onto the transit street.

---

## 5. OPTIMIZE TRANSIT STOP LENGTHS

---

- What it is:** Providing sufficient space at transit stops to allow all doors of transit vehicles to align with curb or boarding island and to allow multiple transit vehicles to serve stops concurrently.
- How it works:** Where transit stops serve multiple transit routes and/or routes with frequent service, transit stops would be designed to accommodate multiple transit vehicles at the same time, thereby reducing the delay associated with a second transit vehicle waiting to access a transit stop to pick-up and drop-off customers.
- Application:** Optimal transit stop length depends on multiple factors, including service frequency, vehicle type and location of stop. Typical approximate lengths for bus stops to accommodate two buses are shown in the table below. These lengths allow buses to pull into the transit zone parallel to the curb, and smoothly pull out of the zone. Far-side zones located after a right turn have a longer recommended length to allow the bus to straighten out after completing the turn.

Stop Position	Type of Bus and Appropriate Zone Length (Ft.)				
	30'	40'	2x40'	60'	2x60'
Midblock	100	120	185	140	205
Nearside	80	100	145	120	185
Farside	50	80	125	100	165
Farside* (After right turn)	100	120 to 140	160 to 180	140 to 160	200 to 220

*\*While suggested zone lengths are listed for zones after turns, the appropriate length varies broadly based on vehicle type (trolley or biodiesel) and lane configuration*

- Estimated Cost:** \$3,000 per transit stop.
- Time Savings:** Estimated average travel time savings of 2 seconds per transit stop (2 seconds is assumed but a more precise estimate could be made of how much delay each bus typically spends waiting for a bus ahead of it to conduct loading activities.)
- Challenges:** May require removal of on-street parking.

---

## 6. CONVERT FLAG STOPS TO TRANSIT ZONES

---

- What it is:** Converting flag stops to transit zones allows buses to pull into the zone to serve customers directly at the curb, rather than from the street.
- How it works:** Converting flag stops to transit zones can reduce transit travel times by allowing customers to be picked-up and dropped-off at the curb instead of in the street. Transit zones also provide transit operators with a clear line-of-sight to see waiting customers and to pull alongside the curb, improving transit accessibility and

customer convenience. Allowing customers to board directly from the curb reduces the height that customers must go up to board the vehicle, and aids in the deployment of the ADA ramp.

- Application:** At lightly-used transit stops. Not recommended at moderately- to highly- used transit stops. (Transit bulbs may be more appropriate for those locations.)
- Estimated Cost:** \$3,000 per transit stop.
- Time Savings:** Estimated travel time savings of 5 seconds per transit stop is assumed to reflect that most buses will no longer have to slow down to ensure that the operator can see any waiting customers, and customers will not need as much time to board the bus as they will have direct access to the bus from the curb.
- Challenges:** May require removal of on-street parking. Additionally, establishing a transit zone can add delay if buses have difficulty pulling out of the zone back into traffic.

---

## 7. ESTABLISH TRANSIT-ONLY LANES

---

- What it is:** A transit-only lane is a travel lane that is dedicated for the exclusive use of transit vehicles.
- How it works:** Transit-only lanes can reduce transit travel times by allowing transit vehicles to bypass traffic congestion and avoid conflicts with other vehicles in mixed travel lanes. Non-transit vehicles are typically permitted to enter transit-only lanes to access curbside parking or to complete a turn, unless specifically prohibited. Transit-only lanes could be dedicated full-time or only for certain hours of the day, such as during peak traffic hours. For example, transit-only lanes may be created in parking lanes with peak-period parking restrictions.
- Application:** Streets with space for two or more travel lanes in the same direction where transit vehicles experience congestion delay. Transit-only lanes are typically 11 to 13 feet wide and at least one block long. Contraflow transit lanes can be used on one-way streets with two or more travel lanes by reversing the direction of one of the lanes and limiting access to transit only.
- Estimated Cost:** \$10,000 per block per direction for “Transit Only” pavement markings and signs; \$35,000 per block per direction for a colored-pavement treatment (estimates based on 400-foot block lengths). Coloring transit-only lanes can improve compliance, but requires a significant capital investment and ongoing maintenance.
- Time Savings:** Estimated travel time savings are highly variable depending on traffic conditions. For right-side transit-only lanes, the amount of right-turning traffic and conflicting pedestrian volumes can influence travel time savings. Research in TCRP Synthesis 83 “Bus and Rail Transit Preferential Treatments in Mixed Traffic” suggests transit-only lanes can result widely-varying travel time savings, ranging from 0.5 to 5 minutes per mile. For our analysis, we have converted these per-mile assumptions to a per-block figure assuming 10 blocks per mile, thus a time savings of approximately five to 30 seconds or more per intersection approach.

**Challenges:** Impacts can include diversion of traffic to other streets, removal of on-street parking, or increased delay to other modes, including pedestrians if longer signal cycles are required to accommodate traffic demand with fewer lanes. Transit-only lanes require ongoing enforcement to maximize effectiveness.

---

## 8. ESTABLISH TRANSIT QUEUE JUMP/BYPASS LANES

---

**What it is:** A transit queue jump/bypass lane allows transit vehicles to bypass general traffic stopped at a signalized intersection and move through the intersection with an exclusive traffic signal phase ahead of general traffic.

**How it works:** Transit queue jump/bypass lanes can reduce transit travel times by providing priority to transit vehicles at signalized intersections. A transit queue jump/bypass lane may be created by restricting parking at an intersection approach to create a restricted lane for transit vehicles and right-turning vehicles.

**Application:** Transit queue jump/bypass lanes are typically 11 to 13 feet wide and 100 to 150 feet long. Transit queue jump/bypass lanes should be applied on a case by case basis depending on roadway geometry constraints and travel time savings opportunities.

**Estimated Cost:** \$10,000 per intersection for simple bypass lanes using signs and pavement markings only. Queue jumps that require traffic signal hardware changes or more complicated roadway striping changes will have higher capital costs ranging from \$25,000 to \$200,000.

**Time Savings:** Highly variable based on the application. Travel time savings depend on traffic queue lengths and length of bypass lane provided. At intersections with high right-turn volumes and high conflicting pedestrian volumes, potential travel time savings will be reduced.

**Challenges:** Removal of on-street parking. Increased delay to other modes resulting from exclusive transit signal phase.

---

## 9. ESTABLISH DEDICATED TURN LANES

---

**What it is:** Dedicated turn lanes can reduce transit travel times by providing a dedicated space for turning vehicles to queue at an intersection approach without blocking the thru-movement of transit vehicles and other traffic.

**How it works:** When vehicles are waiting to turn, they can be delayed by opposing traffic or pedestrians crossing the street. Providing dedicated turn lanes allows turning vehicles to queue without blocking thru traffic. A dedicated turn lane at an intersection controlled by a traffic signal may also include modifying the traffic signal phasing to provide a protected phase for turning traffic.

**Estimated Cost:** \$3,000 at intersections where no signal improvements are required. \$30,000 to \$300,000 per installation if signal hardware changes are required, with higher costs reflecting locations that require new underground conduits.

**Time Savings:** Estimated travel time savings of 5 to 30 seconds per intersection approach, depending on traffic volumes and pedestrian activity.

- Application:** Dedicated turn lanes are typically 9 to 12 feet wide and 100 to 150 feet long, but can be as short as 50 feet. Dedicated turn lanes are typically established at intersections with adequate roadway width and high turning traffic volumes and/or high levels of conflicting pedestrian activity causing turn delay.
- Challenges:** Removal of on-street parking. Some streets do not have the necessary width to provide dedicated turn lanes. Adding dedicated turn lanes may conflict with other planning goals, such as efforts to shorten pedestrian crossings by adding pedestrian bulbs. Adding exclusive turn phases to a traffic signal may not always be feasible or may degrade the operation of an intersection for other users.

## 10. WIDEN TRAVEL LANES THROUGH LANE REDUCTIONS

- What it is:** Widening travel lanes can decrease transit travel times and improve reliability by reducing friction with other vehicles, eliminating the need for buses and other large vehicles to straddle two travel lanes and providing additional space for maneuvering around parking vehicles.
- How it works:** On streets with two or more travel lanes in the same direction, removing one travel lane would allow for widening of the remaining lanes.
- Estimated Cost:** \$10,000 per block per direction.
- Time Savings:** Estimated travel time savings of 5 to 30 seconds per intersection approach, depending on traffic volumes, double parking, and parking maneuvers.
- Application:** Streets with two or more travel lanes in the same direction where transit vehicles are delayed due to narrow lane widths and parking maneuvers or loading activity.
- Challenges:** Removing travel lanes to provide wider lanes can result in an overall decrease in vehicle capacity on a street which may result in diversion of vehicular traffic to other streets, depending on the current traffic volumes relative to the available capacity.

## 11. IMPLEMENT TURN RESTRICTIONS

- What it is:** Turn restrictions can reduce transit travel times by preventing turning vehicles from blocking the thru-movement of transit vehicles and other traffic.
- How it works:** At locations where heavy traffic and/or pedestrian volumes result in few gaps for left-turning vehicles, turn restrictions would enhance overall intersection capacity, improve transit and traffic flow and reduce conflicts between turning vehicles and other traffic and pedestrians. Left-turn restrictions would generally be applied on two-way streets where right-of-way is not available to provide dedicated left-turn lanes (see Toolkit measure 9 above), or where left-turning vehicles are required to cross or enter a transit lane to complete a turn. Turn restrictions can be implemented part-time or full-time. In locations where turn restrictions are already in place, consistent hours would be considered at multiple intersections along a corridor to improve compliance and clarity.

Estimated Cost:	\$3,000 per intersection where implemented through signage and striping. Higher capital costs if concrete islands or other infrastructure is constructed to prevent illegal left turns.
Time Savings:	Estimated travel time savings of 5 to 30 seconds per intersection approach, depending on traffic volumes and pedestrian activity.
Application:	Intersections with turn delay resulting from turning traffic waiting for gaps in opposing traffic or conflicting pedestrian activity.
Challenges:	Restricting turns can impact local circulation and require vehicles to travel further to access destinations.

---

## 12. WIDEN TRAVEL LANES THROUGH PARKING RESTRICTIONS

---

What it is:	Widening travel lanes through parking restrictions can reduce transit travel times by eliminating the need for buses and other large vehicles to straddle two travel lanes, by reducing delays associated with parking maneuvers and by providing additional space for through-moving transit vehicles.
How it works:	On streets with narrow travel lanes and on-street parking, removing parking full-time or during certain hours of the day, such as during peak traffic hours, can allow for widening of the travel lanes and removal of conflicts with parking maneuvers and loading activity. Parking lanes are typically seven to nine feet wide.
Estimated Cost:	\$10,000 per block per direction.
Time Savings:	Estimated travel time savings of 5 to 30 seconds per intersection approach, depending on traffic volumes, double parking, and parking maneuvers.
Application:	Streets with on-street parking where transit vehicles are delayed due to narrow lane widths and parking maneuvers or loading activity.
Challenges:	Removal of on-street parking.

---

## 13. INSTALL TRAFFIC SIGNALS AT UNCONTROLLED AND TWO-WAY STOP-CONTROLLED INTERSECTIONS

---

What it is:	Adding traffic signals at uncontrolled intersections or replacing two-way STOP sign intersection controls with traffic signals.
How it works:	Installing traffic signals at some intersections that are uncontrolled or have STOP signs requiring only vehicles on the street without transit to stop can improve intersection safety and/or pedestrian access to transit stops. Traffic signals can clarify the right-of-way for pedestrians while minimizing travel time delays for transit vehicles.
Estimated Cost:	\$400,000 per intersection to design and construct.
Time Savings:	None.
Application:	The California Manual on Uniform Traffic Control Devices provides general warrants for the use of traffic signals and the SFMTA has internal guidelines for the installation

of STOP signs and traffic signals. Traffic signals are generally recommended along streets with relatively heavy traffic volumes, especially when adjacent intersections have traffic signals. Traffic signals would include pedestrian countdown signals and marked crosswalks. Traffic signals are typically fixed time, but may be actuated at low-volume intersections.

**Challenges:** Traffic signals may be perceived in some neighborhoods as speeding up traffic or changing the residential character of a neighborhood street. Safety and operational factors have to be considered before a traffic signal is recommended.

#### 14. INSTALL TRAFFIC SIGNALS AT ALL-WAY STOP-CONTROLLED INTERSECTIONS

- What it is:** Replacing all-way STOP sign intersection controls with traffic signals.
- How it works:** Installing traffic signals at all-way STOP-controlled intersections can reduce transit travel times by allowing transit vehicles to take advantage of planned transit signal priority improvements that could allow traffic signals to be programmed to hold green signals for approaching transit vehicles.
- Application:** The California Manual on Uniform Traffic Control Devices provides general warrants for the use of traffic signals and the SFMTA has internal guidelines for the installation of STOP signs and traffic signals. Traffic signals are generally recommended along streets with relatively heavy traffic volumes, especially when adjacent intersections have traffic signals. Traffic signals would include pedestrian countdown signals and marked crosswalks. Traffic signals are typically fixed time, but may be actuated at low-volume intersections.
- Estimated Cost:** \$400,000 per intersection to design and construct.
- Time Savings:** Estimated travel time savings of 10 to 30 seconds per intersection approach. Replacing STOP signs with traffic signals is generally expected to result in lower travel time savings along streets with lower traffic volumes, with savings primarily resulting from transit vehicles not having to come to a complete stop. Replacing STOP signs with traffic signals at congested intersections may result in higher travel time savings resulting from additional reductions in congestion delay. There may be more benefit to replacing STOP signs with traffic signals along light rail lines due to the slower acceleration/deceleration rates of light rail vehicles. Traffic signals can increase delay for transit in some situations, so STOP-controlled intersections should be reviewed for conversion to traffic signal control on a case-by-case basis.

Scenario	Assumed Time Benefit
Bus at low volume intersection	10 seconds
Bus at moderate volume major and low volume minor street, actuated; Rail at low volume intersection	20 seconds
Bus at congested major street; Rail at moderate volume or congested major street	30 seconds

Challenges: Traffic signals may be perceived in some neighborhoods as speeding up traffic or changing the residential character of a neighborhood street. Safety and operational factors have to be considered before a traffic signal is recommended.

---

## 15. REPLACE ALL-WAY STOP-CONTROLLED INTERSECTIONS WITH TRAFFIC CALMING MEASURES

---

What it is: Removing STOP signs and adding traffic calming measures at intersection approaches with transit service can reduce transit travel time along a corridor by allowing transit vehicles to proceed slowly through intersections without coming to a complete stop.

How it works: To maintain traffic control, STOP signs along streets where transit is not traveling (non-transit streets) would typically remain to create a two-way STOP controlled intersection, but may be removed depending on the type of traffic calming treatment. Traffic calming measures would be considered to maintain pedestrian safety – such measures would generally involve improving crossing conditions for pedestrians, slowing traffic, and reducing right-of-way conflicts between pedestrians and other traffic. Examples of traffic calming measures that could be applied in conjunction with STOP sign removal include, but are not limited to, the following:

- Traffic circles;
- Pedestrian refuge islands;
- Pedestrian bulbs;
- Median extensions through an intersection;
- Flashing beacons to alert roadway users of pedestrian crossings;
- Parking restrictions at intersection approaches to improve sight distance;
- Enhanced crosswalk markings and signs; and
- Speed humps.

Estimated Cost: Varies depending on level of traffic calming included. Low-end costs of \$5,000 per intersection for simple sign and striping improvements. High-end costs may exceed \$100,000 per intersection if hardscape elements such as pedestrian bulbs or traffic circles are included.

Time Savings: Estimated travel time savings of 10 to 30 seconds per intersection approach. Lower travel time savings anticipated along streets with lower traffic volumes, with savings primarily resulting from transit vehicles not having to come to a complete stop. Higher travel time savings anticipated at congested intersections resulting from additional reductions in congestion delay. Travel time savings are anticipated to be highest at intersections without transit stops.

Application: The California Manual on Uniform Traffic Control Devices provides general warrants for the use of STOP signs and the SFMTA has internal guidelines for the installation of STOP signs. Engineering studies would be required to determine which alternative measures are most appropriate if STOP signs were to be removed and not replaced by

traffic signals, depending on factors such as vehicle and pedestrian volumes, sight distances, street network and collision history.

**Challenges:** STOP sign removal would require significant outreach to the neighborhood. Previous STOP sign removals in San Francisco have been reversed over time. STOP sign removal would require notification to motorists and pedestrians that traffic control pattern has changed. There may be pedestrian and vehicular safety concerns from restoration of two-way STOP controls, as well as concerns about increased speeding through the intersection vehicles are no longer required to stop.

---

## 16. INSTALL PEDESTRIAN REFUGE ISLANDS

---

**What it is:** Pedestrian refuge islands are raised islands in the street that provide space for pedestrians to wait while crossing a street.

**How it works:** Pedestrian refuge islands can reduce transit travel time by shifting travel lanes toward the curb and eliminating the need for buses to exit and re-enter the flow of traffic to access curbside transit stops. Pedestrian refuge islands can also improve pedestrian safety by increasing pedestrian visibility and minimizing pedestrian exposure to vehicular traffic.

**Application:** Pedestrian refuge islands are preferably a minimum of 6 feet wide, but can be as narrow as 4 feet wide. For additional information on pedestrian refuge islands, see Section 5.4 of the San Francisco Better Streets Plan.

**Estimated Cost:** \$25,000 per island, but can be more expensive if they require significant hydraulic or grading work.

**Time Savings:** Estimated travel time savings of 2 seconds per direction per intersection at signalized intersections without transit stops – this savings is estimated to result from changes to traffic signal timing providing additional green time for the transit street as the amount of time required for the non-transit cross street is reduced due to the shorter pedestrian crossing distance. Estimated travel time savings of 5 seconds per direction per intersection at locations with transit stops where travel lanes are shifted toward the curb and eliminate the need for buses to exit and re-enter the flow of traffic to access curbside transit stops.

**Challenges:** On-street parking removal. Where pedestrian refuge islands result in transit vehicles blocking travel lanes while serving transit stops on streets with one travel lane in a given direction there is the potential for intersections to become unintentionally blocked by motorists following the transit vehicle (far-side stop) or for motorists to pass stopped transit vehicles on the left using an opposing traffic lane (near-side stop). Some customer loading maneuvers can require more than a minute to be completed. For this reason pedestrian refuge islands on two-lane roadways should be applied with caution. Factors to consider include the volume of affected through traffic, intersection traffic controls, and the frequency of transit service. Pedestrian refuge island design should be coordinated with the fire department to ensure access to fire hydrants is maintained and to review potential impacts to emergency response times.

---

## 17. INSTALL PEDESTRIAN BULBS

---

What it is:	Pedestrian bulbs are sidewalk extensions at non-transit stop intersection corners, typically about the same width as the adjoining parking lane.
How it works:	Pedestrian bulbs at signalized intersections can reduce transit travel time by reducing the roadway crossing distance, which can provide flexibility in traffic signal timing and reduce the likelihood of transit vehicles arriving on a red signal indication. Pedestrian bulbs can also improve pedestrian safety by shortening the street crossing distance, improving pedestrian visibility and reducing the speed of turning traffic.
Application:	Dimensions will vary by site, but typical pedestrian bulbs are 6 feet wide and use 10-foot and 20-foot transition radii. See DPW Standard Plans 87,175 for typical dimensions of transitions, available at <a href="http://www.sfdpw.org/ftp/uploadedfiles/sfdpw/boe/87.175.pdf">http://www.sfdpw.org/ftp/uploadedfiles/sfdpw/boe/87.175.pdf</a>
Estimated Cost:	\$50,000 to \$200,000 per bulb, depending on the location. Higher end estimates are based on requirements to relocate utilities, sewer catch basins, and fire hydrants. Decorative sidewalks and sub-sidewalk basements present the most significant design complications. A mid-range cost of \$100,000 will be assumed in this report.
Time Savings:	Estimated travel time savings of 2 seconds per pedestrian bulb - this savings is estimated to result from changes to traffic signal timing providing additional green time for the transit street as the amount of time required for the non-transit cross street is reduced due to the shorter pedestrian crossing distance.
Challenges:	On-street parking removal. Pedestrian bulb design should be coordinated with the fire department to ensure access to fire hydrants is maintained and to review potential impacts to emergency response times.

---

## 18. WIDEN SIDEWALK

---

What it is:	Extending sidewalks into street to provide additional pedestrian space.
How it works:	Widening sidewalks can improve conditions for pedestrians and transit passengers by providing additional pedestrian space and space for transit shelters, landscaping and other amenities. Sidewalk widening can also improve pedestrian safety by shortening the street crossing distance.
Estimated Cost:	Varies widely depending on dimensions and requirements to relocate utilities, sewer catch basins, and fire hydrants.
Time Savings:	None.
Application:	Sidewalk widening may require removal of parking or mixed-flow travel lanes on streets with multiple lanes in the same direction. Widths vary depending on site-specific conditions.
Challenges:	Removal of on-street parking.

## Introduction

Data used to build the following 2015 PM-peak hour (5:00 – 6:00 pm) VISSIM models for the Van Ness BRT Corridor Study are outlined in this Data Portfolio.

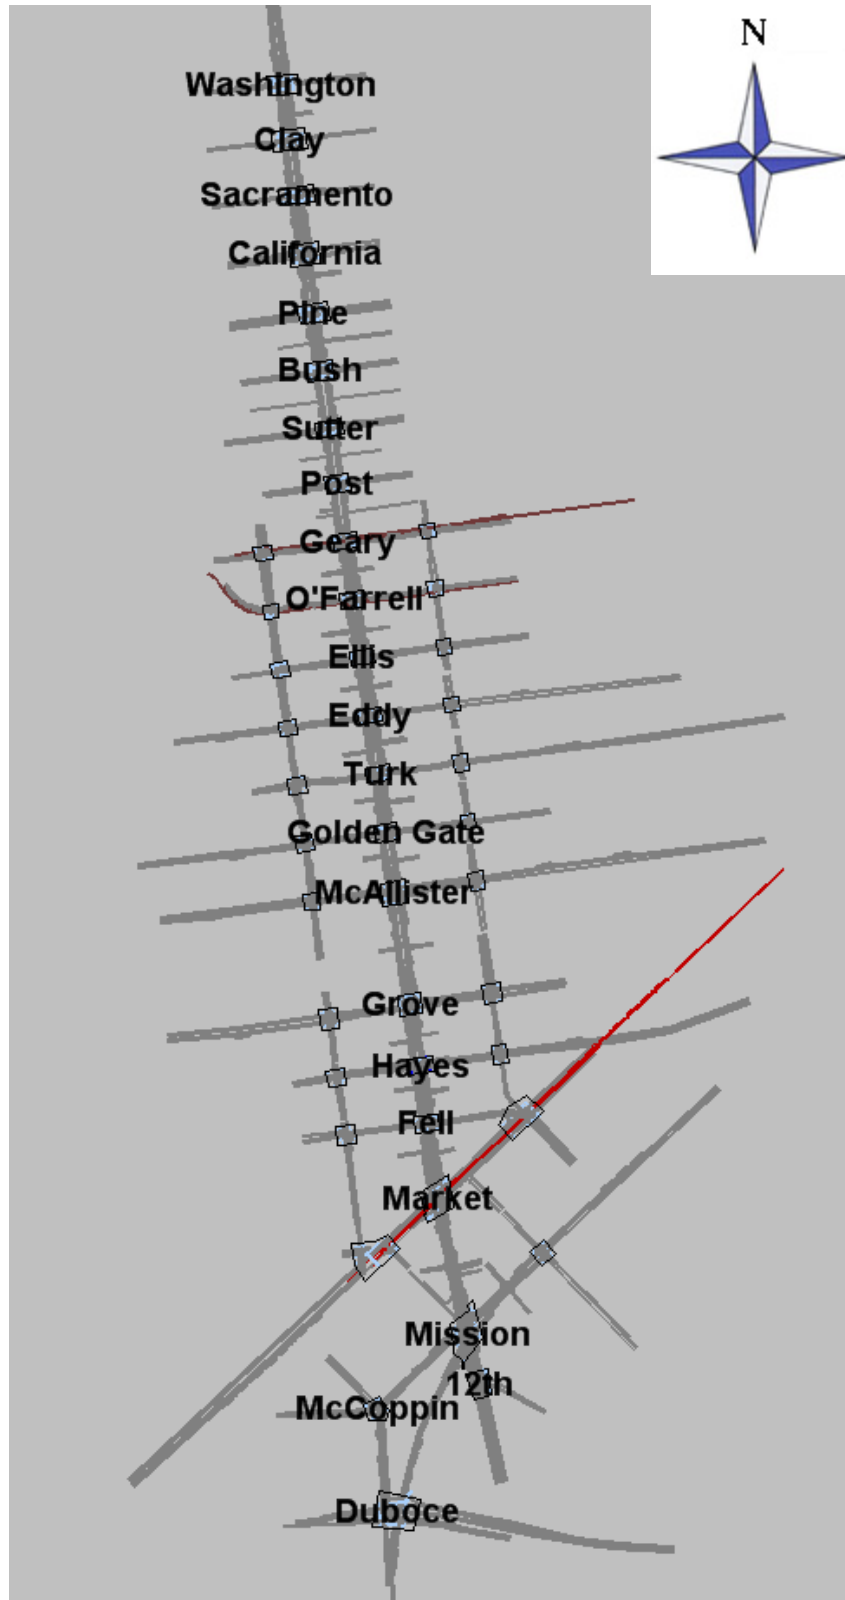

- No Project
- Side BRT (curb lane)
- Center A BRT
- Center B BRT (Center A + left turns eliminated along Van Ness)

## Study Area

The study area extends along Van Ness Avenue from Clay Street to Mission Street/Otis Street and then along Otis Street southwest to Duboce Avenue/13 Street, encompassing 21 study area signals (refer to Exhibit 1). The actual modeled area was expanded to Washington (not a study area signal) - one signalized intersection beyond the northern most study signal - to model platooned arrivals along Van Ness that result from progression. Non-study area signals (22) from the earlier BRT Feasibility Study were also included for similar reasons as the signal at Washington. The VISSIM model included the 43 signals listed in Exhibit 2.

Mid-block sinks and sources were also added to the study area. These sinks and sources were modeled as mid-block driveways to account for differences between the volume leaving an upstream signal and arriving at a downstream signal.

Exhibit 1. Study Area

**Lane Geometry and Speed Data**

*Source: CHS (Lane Geometry via Synchro File), PTV (Calibrated Speeds)*

Lane geometry for each study area signal is provided in Appendix A. The Side and Center BRT lanes extended from Clay to Mission.

In addition, transit lanes are located on Sutter, Post, Geary, O'Farrell and Market. With the exception of market, these transit lanes are located in the right most travel lane. General purpose traffic making a right turn on these four streets is permitted to use the transit lanes. On Market, the transit lane is located in the center of the roadway with one lane in each direction. General purpose traffic is not permitted to enter the transit lanes on Market.

Calibrated speed settings in the 2007 Existing Conditions model were carried forward in the 2015 models with the exception of the Center scenarios. An assumption was made that BRT operators would desire to travel at a slightly faster speed (+5 mph) in the exclusive BRT lanes since the exclusive lanes eliminated a number of unexpected events (e.g., autos making abrupt lane changes, autos unexpectedly stopping to park) that are common in general purpose travel lanes within a downtown environment. The desired speeds coded in VISSIM are provided in Exhibit 3.

**Exhibit 3. VISSIM Calibrated Desired Speed Settings**

Movements	2015 Scenario			
	No Project	Side BRT	Center A BRT	Center B BRT
<b>Southbound</b>				
#47	11.5	11.5	16.5	16.5

**Volumes**

**Traffic Volumes**

Source: CHS (Synchro File)

Balanced PM-peak hour traffic volumes are located in Appendix A. Mid-block sinks and sources were used to balance volumes between signals.

**Truck Percentages**

Source: CHS (Synchro File)

Truck percentages were coded as 2% throughout the study area.

**Pedestrian Volumes**

Source: SFCTA

Pedestrian volumes for the 2015 No Build and 2015 BRT scenarios are shown in Exhibits 4 and 5.

## On-Street Parking

Source: SFCTA

To account for the effects of on-street parking along Van Ness Avenue, parking maneuvers were modeled along each block face. The number of parking vehicles during the PM-peak hour (5-6 pm) for each 2015 scenario is shown in Exhibit 6 and 7. A parking vehicle reflects two movements – pulling into a parking space and exiting a parking space.

### Exhibit 6. Southbound Parking Vehicles

<sup>1</sup>Each vehicle represents two movements – entering and exiting a parking space.

<sup>2</sup>These block faces are located on Mission.

## **Non-Yielding Vehicles to Buses Exiting a Stop**

*Source: SFCTA*

As observed along Van Ness, a portion of the motorists do not yield to buses exiting a pull-out stop (bus bay). Field data revealed that roughly 57% of cars did not yield to buses exiting a stop. This same percentage was coded in VISSIM for the 2015 scenarios.

## **Signal Timing**

*Source: CHS (Synchro)*

CHS provided Synchro files with the signal timing data for each scenario modeled in VISSIM (refer to Appendix A). Fourth Dimension (a subconsultant to PTV) recoded the Synchro signal timings for the study area signals into the D4 virtual controllers. The D4 controllers were then incorporated in VISSIM. The D4 controllers reflect the actual timing plans and TSP logic that will be implemented in the field, thus, increasing the accuracy of the simulation to replicate field conditions.

## **Transit**

### **Routes, Vehicle Types, Frequencies**

*Source: SFCTA*

Exhibit 8 lists all transit routes modeled in the study area. The exhibit also identifies the transit vehicle types and frequencies. Transit routes are shown graphically in Exhibits 9 and 10.

### **Ridership**

*Source: SFCTA*

Exhibit 11 summarizes the average ridership per trip estimated for each non-BRT route. BRT ridership data is summarized in Exhibits 12 - 14.

Ridership levels were held constant for all non-BRT routes traveling through the study area for modeling purposes. The number of passengers on BRT routes, however, varied by the boarding and alighting activity estimated at each stop. Including boardings and alightings enables the model to capture the influence of bus bunching along the BRT routes. Ridership was also a key component in estimating person delay.

### **BRT Stops**

*Source: SFCTA*

BRT stop locations are also listed in Exhibits 12 - 14.

<sup>2</sup>FS = Far-Side; NS = Near-Side

**Dwell Times**

Source: SFTCA (boardings + alighting), PTV (HCM boarding + alighting rates)

Dwell time for routes 47 and 49 were calculated in VISSIM based on the number of passengers boarding and alighting each bus at each stop. The volume of boarding and alighting passengers at each stop is shown in Exhibits 12 - 14.

Boarding and alighting rates were extracted from Highway Capacity Manual (HCM 2000) and entered in VISSIM. The corresponding information is shown in Exhibit 15.

**Exhibit 15. Boarding and Alighting Rates**

Bus Characteristics	Route	
	#47 <sup>1</sup>	#49
Number of front doors	1	1
Number of rear doors	1	2
Boarding service rate (pax/sec)	2.80	2.80
Alighting service rate (pax/sec)	1.85	1.10

<sup>1</sup>The #47 vehicle type changed from a 40-foot standard bus in the 2015 No Project scenario to a 60-foot articulated bus in all 2015 BRT scenarios. Therefore, the characteristics of the #49 above applied to the #47 in all BRT scenarios.

The clearance time that reflects the time for the doors to open after the bus is stopped and the time between when the doors are closed and the bus driver is ready to leave the stop was also modeled. The HCM 2000 provides a clearance time range of 2 - 5 seconds. The value applied in VISSIM was 5 seconds.

Dwell times for the BRT scenarios were reduced by a factor of 10% to account for implementing a Proof-of-Payment (POP) system that allows for all door boarding.

### **Schedule Reliability**

Source: SFCTA

Schedule reliability data was provided by SFCTA based on earlier field data collected during the PM-peak period (additional details provided in the 2007 Existing Conditions Data Portfolio). The schedule reliability data for routes #47 and #49 are summarized in Exhibit 16.

#### **Exhibit 16. Schedule Reliability Distributions**

<b>Schedule Reliability</b>	<b>#47</b>	<b>#49</b>	<b>All Other Routes</b>
Average Delay (seconds)	130	67	60
Standard Deviation (seconds)	214	187	20

The schedule reliability distributions were applied in VISSIM by coding a “dummy” stop at the point where each route enters the network. Each bus was required to dwell at a “dummy” stop according to the distributions shown in Exhibit 16. The dummy stop added variability to the buses arrival at downstream stops which more closely reflects reality than applying the desired departure times in a schedule or a uniform headway.

The schedule reliability distributions (average and standard deviation) for the #47 and #49 were reduced by 5% to reflect increased supervision and AVL line management. This reduction was applied to all 2015 scenarios include the No Project scenario.

### **Bus Bay Utilization**

Source: SFCTA

Data is provided in the 2007 Existing Conditions Data Portfolio that describes the frequency at which the #47 and #49 buses block a lane when a bus bay exists. 40-foot buses blocked the lane when a bay exists 28% of the time while a 60-foot bus blocked a lane 50% of the time. These same factors were applied in the 2015 No Project scenario. They were not applied in the Side and Center scenarios since the buses stopped in the BRT lane.

## Diversion Analysis

# MEMORANDUM

DATE: May 18, 2009  
TO: Margaret Cortes  
FROM: Chi-Hsin Shao  
RE: Van Ness Avenue Diversion Analysis, Updated

---

This memo outlines the process we will use to refine the diversion data we received from SFCTA. The data provided by SFCTA were based on the runs from SF CHAMP, SFCTA's travel forecasting model, which show approximately 6-49 percent of the Van Ness Avenue diverted trips were actually diverted within the study area. We recognize that the SF CHAMP model does not recognize the steepness of roadway grades in San Francisco, and roadway levels of services, thus, model traffic assignment needs manual adjustments.

## Step 1 – Initial Assessment

CHS will assess the origins and destination patterns for the trips to, from, and within Van Ness Avenue. SFCTA will provide 20 by 20 zonal trip tables from the select link analysis for three segments in the Van Ness corridor study area (Lombard to California, California to Eddy, and Eddy to Market). Based on the travel pair, CHS will assess whether the model screenline analysis can be adjusted.

## Step 2 – Traffic Diversion Refinement

CHS will use the following three criteria to assess whether the model assignment was reasonable and can be modified as seen in Table 1 and Table 2 below:

- Connectivity – If a north-south link in a section is discontinuous (Connected = 0 and highlighted in purple) because of a park, then it would be regarded as undesirable for diversion. This means that the trips that were diverted to this link by the SF CHAMP model will be diverted back to links within the study area
- Grade – If the north-south link was continuous but there are more than two blocks along a north-south link in a section with more than 18% grade (highlighted in blue), it will be regarded as undesirable for diversion. This means that the trips that were diverted to this link by the SF CHAMP model will be diverted back to links within the study area.
- Levels of Services – The SFCTA monitoring counts will be used for this analysis. If the north-south link was continuous and did not have more than two block with 18% grade, but the LOS is at F level (highlighted in orange), it will be regarded as undesirable for diversion. This means that the trips that were diverted to this link by the SF CHAMP model will be diverted back to links within the study area.

All the trips diverted back to the study area from streets east of Van Ness will be added to Larkin St and Hyde St uniformly (50%-50% volume split) if both streets are continuous in this section. If one of

them is discontinuous, then all the diverted trips will be added to the continuous street.

All the trips diverted back to the study area from streets west of Van Ness will be added to Gough St and Franklin St uniformly (50%-50% volume split) if both streets are continuous in a section. If one of them is discontinuous, then all the diverted trips will be added to the continuous street.. In order to keep the analysis simple, no traffic volumes will be added to Polk St and its diverted volumes will remain unchanged.

These diverted trips to Larkin St, Hyde St, Gough St and Franklin St will be added to the Van Ness trips already diverted to these streets by the SF CHAMP model for 2015 Center and 2015 Side scenarios as seen in Figure 1 and 2. These total diverted trips (trips diverted from Van Ness by SF CHAMP model + trips diverted in the diversion analysis performed above) will replace the diverted trips from the SF CHAMP model in the volume balancing spreadsheets at locations where the north-south streets of Larkin St, Hyde St, Gough St and Franklin St intersect the east-west streets of Lombard St, California St, Eddy St and Market St. The volumes at these intersections will be balanced and this will be used as input into the 2015 Center and 2015 Side Synchro models.

### Findings

#### **For 2015 Center**

The northern section between Lombard and Eddy experiences a large diversion of volume in the diversion analysis (between 40 to 100 vehicles). The central and southern sections experience moderate diversion of volume in the diversion analysis (between 0 and 70 veh).

#### **For 2015 Side**

The northern section between Lombard and Eddy experiences a large diversion of volume in the diversion analysis (between 40 to 70 vehicles). The central and southern sections experience moderate diversion of volume in the diversion analysis (between 0 and 55 vehs).

## Vehicular Traffic Volume Balancing Memorandum

## Balancing Traffic Volumes for Future Scenarios

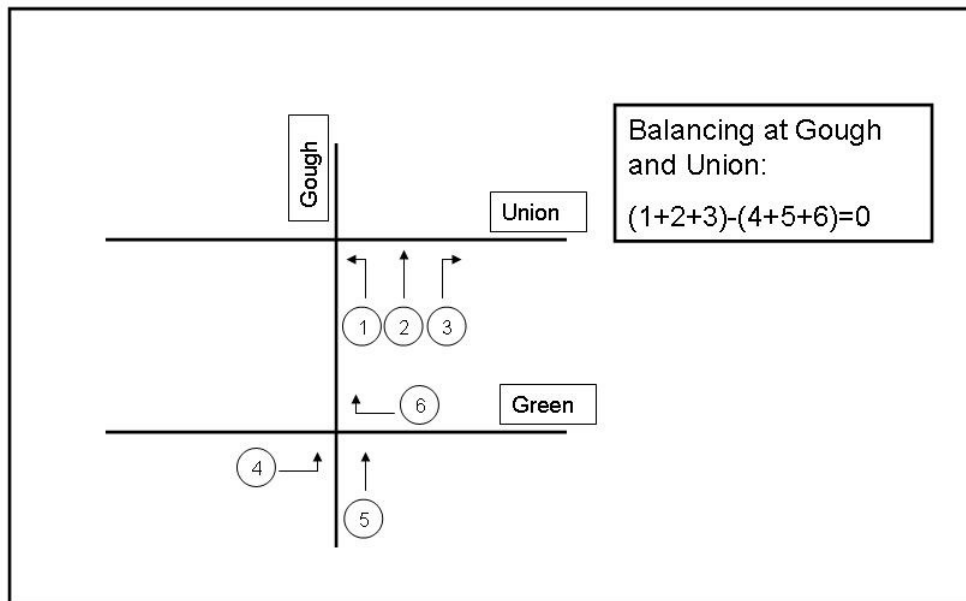

### *No Build Scenario*

1. The 2007 balanced volumes were used to grow both 2015 Baseline and 2035 Baseline volumes to minimize cumulative estimation errors.
2. For all movements the growth factor utilized was an average of the upstream and downstream link growth factors for a particular movement to account for upstream and downstream growth factors. Figure below shows an example.

In this example the NBR turn growth factor at Franklin and Broadway was calculated by averaging the growth factor for NB Franklin approach from the TA model (1.12) at the current intersection and the growth factor for the EB Broadway approach from the TA model (1.07). This is because Broadway and Van Ness intersection is the upstream intersection for the right turning vehicles from NB Franklin @ Broadway.

3. Once a future scenario traffic volume was calculate, three iterations of volume balancing were conducted. In the first iteration, the Thru volumes along the N-S corridor approaches were balanced. This was done such that the direction inflow volume at the current intersection minus the directional outflow at the downstream intersection equaled zero. For example at NB Gough @ Union, the NB inflow (NBR+NBT+NBL) at NB Gough approach - the NB outflow from Gough @ Green (NBT+EBL+WBR) = 0

The right and left turn volumes were modified while balancing only at locations where the turn volumes were significant w.r.t. the total approach volume.

In the second iteration, the E-W corridor approaches were balanced using the same approach as that for N-S corridors. Any change E-W turn movements affected the N-S balancing as the turn movements fed the N-S approaches.

Hence, a third iteration of balancing was performed where the N-S corridors were again balanced to reach an equilibrium of zero. These volumes were used in the Synchro model for Baseline scenarios.

4. The final step involved calculating the total volumes on the N-S corridors by adding the North Through movements and South Through movements along each N-S corridor. For Baseline, a corridor growth factor was calculated by dividing the Baseline totals for each corridor by 2007 totals for each corridor. These values were compared to the average growth factor for the TA model for each N-S corridor (average of all four sections). The above calculated volumes were input into the Synchro model only if the growth factors from the balanced volumes were similar to the growth factors from the TA model. If the growth factors were not similar, then step 3 is repeated until the growth factors are similar.

### ***Build Scenarios***

1. The balanced 2015 Baseline and 2035 Baseline volumes calculated above were used to estimate the 2015 and 2035 Center and Side volumes respectively.
2. For all movements except Van Ness Avenue turning movements, the growth factor utilized was an average of the upstream and downstream link growth factors for that particular movement similar to Step 2 under No Build scenario above.

3. For the right turn and left turn movements from Van Ness and to Van Ness from E-W streets, growth factors were estimated based on roadway capacity change and TA growth factors. A ratio of the total number of lanes along the current approach and the directional upstream intersection for a tuning movement for a build alternative and corresponding year baseline was estimated. For example at Van Ness and Union NBL under Center Lane BRT alternative, there would be 1 NBL lane, 3 NBT lanes and 2 WBT lanes (Total 6 lanes) under Baseline condition. For the Center scenario, there would be 1NBL lane, 2 NBT lanes and 2 WBT lanes (total of 5 lanes). Thus, it was assumed that 5/6 of the NBL trips would desire to grow based on Van Ness NB GF and the remaining 1/6 trips would desire to grow based on Union WB GF. Please note that the SBR turn was not considered in this calculation as it did not affect the desirability of a vehicle making a NBL turn. Also, please note that the left turn and right turn storage lanes were considered during these calculations.
4. Next, traffic volumes were balanced iteratively as discussed under Step 3 of No Build scenario above.
5. Additional volume balancing was performed for build alternatives to account for the diversion analysis as follows:
  - a. The difference between balanced build and balanced No Build volumes were calculated for each movement. The volumes estimated based on diversion analysis then replaced the difference in volumes calculated at appropriate locations.
  - b. The Center and Side volumes were recalculated by adding the No Build volumes and the difference volumes estimated in Step 5a above.
  - c. The three iteration volume balancing discussed under Step 3 of No Build scenario was performed again.
  - d. For locations where the left turns were removed along Van Ness in the Center and Side scenarios, the volumes from Step 5c above were manually reassigned as follows
    - Approximately one-third of the left turning volume (33%) was diverted to the upstream intersection within 2 blocks of the original destination if available
    - Approximately one-third of the left turning volume (33%) was diverted to the downstream intersection within 2 blocks of the original destination if available
    - The remaining trips (34%) would circulate the block to arrive westbound or eastbound on the original street. Additionally, if upstream and downstream left-turn opportunities are unavailable within two-blocks of the affected intersection, then traffic would circle the block.
6. Similar to developing the baseline volumes, the final step involved calculating the total volumes on the N-S corridors by adding the North Through movements and South Through movements along each N-S corridor. For Center and Side, the growth factor was calculated by dividing the Center and Side totals for each corridor by Baseline totals for each corridor. These values were compared to the average growth factor for the TA model for each N-S corridor (average of all four sections). The above calculated volumes were input into the Synchro model only

if the growth factors from the balanced volumes were similar to the growth factors from the TA model. If the growth factors were not similar, then steps 4 and 5 are repeated until the growth factors are similar.

**Intersection Summary**

Area Type: Other  
 Cycle Length: 120  
 Actuated Cycle Length: 120  
 Offset: 32 (27%), Referenced to phase 1:SBL and 6:SBT, Start of Green  
 Natural Cycle: 120  
 Control Type: Pretimed  
 Maximum v/c Ratio: 1.09  
 Intersection Signal Delay: 44.4                      Intersection LOS: D  
 Intersection Capacity Utilization 109.0%                      ICU Level of Service H  
 Analysis Period (min) 15  
 ~ Volume exceeds capacity, queue is theoretically infinite.  
 Queue shown is maximum after two cycles.  
 # 95th percentile volume exceeds capacity, queue may be longer.  
 Queue shown is maximum after two cycles.

**Intersection Summary**

Area Type: Other

Cycle Length: 90

Actuated Cycle Length: 90

Offset: 12 (13%), Referenced to phase 2:NESW, Start of Green

Natural Cycle: 90

Control Type: Pretimed

Maximum v/c Ratio: 0.90

Intersection Signal Delay: 19.6

Intersection LOS: B

Intersection Capacity Utilization 73.2%

ICU Level of Service D

Analysis Period (min) 15

# 95th percentile volume exceeds capacity, queue may be longer.

Queue shown is maximum after two cycles.

m Volume for 95th percentile queue is metered by upstream signal.

Splits and Phases: 101: Van Ness Avenue & Market St.

**Intersection Summary**

Area Type: Other  
 Cycle Length: 90  
 Actuated Cycle Length: 90  
 Offset: 76 (84%), Referenced to phase 6:SBT, Start of Green  
 Natural Cycle: 90  
 Control Type: Pretimed  
 Maximum v/c Ratio: 0.99  
 Intersection Signal Delay: 45.9      Intersection LOS: D  
 Intersection Capacity Utilization 71.9%      ICU Level of Service C  
 Analysis Period (min) 15  
 # 95th percentile volume exceeds capacity, queue may be longer.  
 Queue shown is maximum after two cycles.  
 m Volume for 95th percentile queue is metered by upstream signal.

**Intersection Summary**

Area Type:	Other
Cycle Length:	60
Actuated Cycle Length:	60
Offset:	45 (75%), Referenced to phase 2:EBTL, Start of Green
Natural Cycle:	40
Control Type:	Pretimed
Maximum v/c Ratio:	0.88
Intersection Signal Delay:	12.6
Intersection LOS:	B
Intersection Capacity Utilization:	65.0%
ICU Level of Service:	C
Analysis Period (min):	15
# 95th percentile volume exceeds capacity, queue may be longer.	
Queue shown is maximum after two cycles.	

Splits and Phases: 503: O'Farrell St. & Larkin St.

 ~ Volume exceeds capacity, queue is theoretically infinite.  
 Queue shown is maximum after two cycles.  
 # 95th percentile volume exceeds capacity, queue may be longer.  
 Queue shown is maximum after two cycles.  
 m Volume for 95th percentile queue is metered by upstream signal.

**Intersection Summary**

Area Type: Other

Cycle Length: 90

Actuated Cycle Length: 90

Offset: 7 (8%), Referenced to phase 2:NBTL, Start of Green

Natural Cycle: 60

Control Type: Pretimed

Maximum v/c Ratio: 0.89

Intersection Signal Delay: 5.3

Intersection LOS: A

Intersection Capacity Utilization 64.3%

ICU Level of Service C

Analysis Period (min) 15

m Volume for 95th percentile queue is metered by upstream signal.

Splits and Phases: 671: Clay St. & Franklin St.

**Intersection Summary**

Area Type: Other  
 Cycle Length: 60  
 Actuated Cycle Length: 60  
 Offset: 11 (18%), Referenced to phase 6:WBTL, Start of Green  
 Natural Cycle: 45  
 Control Type: Pretimed  
 Maximum v/c Ratio: 0.81  
 Intersection Signal Delay: 11.9      Intersection LOS: B  
 Intersection Capacity Utilization 83.4%      ICU Level of Service E  
 Analysis Period (min) 15  
 # 95th percentile volume exceeds capacity, queue may be longer.  
 Queue shown is maximum after two cycles.  
 m Volume for 95th percentile queue is metered by upstream signal.

**Splits and Phases: 516: Geary St. & Polk St.**

**Intersection Summary**

Area Type: Other  
 Cycle Length: 90  
 Actuated Cycle Length: 90  
 Offset: 52 (58%), Referenced to phase 2:NBSB, Start of Green  
 Natural Cycle: 90  
 Control Type: Pretimed  
 Maximum v/c Ratio: 0.96  
 Intersection Signal Delay: 14.6      Intersection LOS: B  
 Intersection Capacity Utilization 73.6%      ICU Level of Service D  
 Analysis Period (min) 15  
 # 95th percentile volume exceeds capacity, queue may be longer.  
 Queue shown is maximum after two cycles.  
 m Volume for 95th percentile queue is metered by upstream signal.

**Splits and Phases: 661: Sacramento St. & Van Ness Avenue**

**Intersection Summary**

Area Type: Other  
 Cycle Length: 90  
 Actuated Cycle Length: 90  
 Offset: 23 (26%), Referenced to phase 2:NBTL and 6:SBT, Start of Green  
 Natural Cycle: 90  
 Control Type: Pretimed  
 Maximum v/c Ratio: 0.75  
 Intersection Signal Delay: 13.9 Intersection LOS: B  
 Intersection Capacity Utilization 96.3% ICU Level of Service F  
 Analysis Period (min) 15  
 # 95th percentile volume exceeds capacity, queue may be longer.  
 Queue shown is maximum after two cycles.  
 m Volume for 95th percentile queue is metered by upstream signal.

**Splits and Phases: 909: Union St. & Van Ness Avenue**

**Intersection Summary**

Area Type: Other

Cycle Length: 90

Actuated Cycle Length: 90

Offset: 11 (12%), Referenced to phase 1:SBL and 6:SBT, Start of Green

Natural Cycle: 130

Control Type: Pretimed

Maximum v/c Ratio: 1.28

Intersection Signal Delay: 51.3

Intersection LOS: D

Intersection Capacity Utilization 103.6%

ICU Level of Service G

Analysis Period (min) 15

~ Volume exceeds capacity, queue is theoretically infinite.

Queue shown is maximum after two cycles.

# 95th percentile volume exceeds capacity, queue may be longer.

Queue shown is maximum after two cycles.

m Volume for 95th percentile queue is metered by upstream signal.

Splits and Phases: 18: Duboce St. &

**Intersection Summary**

Area Type: Other  
 Cycle Length: 90  
 Actuated Cycle Length: 90  
 Offset: 62 (69%), Referenced to phase 4:NET, Start of Green  
 Natural Cycle: 85  
 Control Type: Pretimed  
 Maximum v/c Ratio: 0.95  
 Intersection Signal Delay: 34.1                      Intersection LOS: C  
 Intersection Capacity Utilization 101.1%                      ICU Level of Service G  
 Analysis Period (min) 15  
 # 95th percentile volume exceeds capacity, queue may be longer.  
 Queue shown is maximum after two cycles.  
 m Volume for 95th percentile queue is metered by upstream signal.

Splits and Phases: 1350: Page St & Market St.

 Analysis Period (min) 15  
 ~ Volume exceeds capacity, queue is theoretically infinite.  
 Queue shown is maximum after two cycles.  
 # 95th percentile volume exceeds capacity, queue may be longer.  
 Queue shown is maximum after two cycles.  
 m Volume for 95th percentile queue is metered by upstream signal.
